## Preface

This is a technical manual for designers and programmers who develop a product using the S1C17W03/W04. This document describes the functions of the IC, embedded peripheral circuit operations, and their control methods.

For the CPU functions and instructions, refer to the “S1C17 Family S1C17 Core Manual.” For the functions and operations of the debugging tools, refer to the respective tool manuals. (Our “Products: Document Downloads” website provides the downloadable manuals.)

## Notational conventions and symbols in this manual

### Register address

Peripheral circuit chapters do not provide control register addresses. Refer to “Peripheral Circuit Area” in the “Memory and Bus” chapter or “List of Peripheral Circuit Control Registers” in the Appendix.

### Register and control bit names

In this manual, the register and control bit names are described as shown below to distinguish from signal and pin names.

XXX register: Represents a register including its all bits.

XXX.YYY bit: Represents the one control bit YYY in the XXX register.

XXX.ZZZ[1:0] bits: Represents the two control bits ZZZ1 and ZZZ0 in the XXX register.

### Register table contents and symbols

Initial: Value set at initialization

Reset: Initialization condition. The initialization condition depends on the reset group (H0, H1, or S0). For more information on the reset groups, refer to “Initialization Conditions (Reset Groups)” in the “Power Supply, Reset, and Clocks” chapter.

R/W: R = Read only bit

W = Write only bit

WP = Write only bit with a write protection using the MSCPROT.PROT[15:0] bits

R/W = Read/write bit

R/WP = Read/write bit with a write protection using the MSCPROT.PROT[15:0] bits

### Control bit read/write values

This manual describes control bit values in a hexadecimal notation except for one-bit values (and except when decimal or binary notation is required in terms of explanation). The values are described as shown below according to the control bit width.

1 bit: 0 or 1

2 to 4 bits: 0x0 to 0xf

5 to 8 bits: 0x00 to 0xff

9 to 12 bits: 0x000 to 0xffff

13 to 16 bits: 0x0000 to 0xffff

Decimal: 0 to 9999...

Binary: 0b0000... to 0b1111...

### Channel number

Multiple channels may be implemented in some peripheral circuits (e.g., 16-bit timer, etc.). The peripheral circuit chapters use ‘n’ as the value that represents the channel number in the register and pin names regardless of the number of channel actually implemented. Normally, the descriptions are applied to all channels. If there is a channel that has different functions from others, the channel number is specified clearly.

Example) T16\_nCTL register of the 16-bit timer

If one channel is implemented (Ch.0 only): T16\_nCTL = T16\_0CTL only

If two channels are implemented (Ch.0 and Ch.1): T16\_nCTL = T16\_0CTL and T16\_1CTL

For the number of channels implemented in the peripheral circuits of this IC, refer to “Features” in the “Overview” chapter.

# 1 Overview

The S1C17W03/W04 is a 16-bit MCU that features low-voltage operation from 1.2 V even though Flash memory is included. The embedded high-efficiency DC-DC converter generates the constant-voltage to drive the IC with lower power consumption than 4-bit MCUs. This IC includes a real-time clock, a stopwatch, an A/D converter, and a PWM timer capable of being used to generate drive waveforms for a motor driver as well as a high-performance 16-bit CPU. It is suitable for battery-driven applications that require an A/D conversion function and timers.

## 1.1 Features

Table 1.1.1 Features

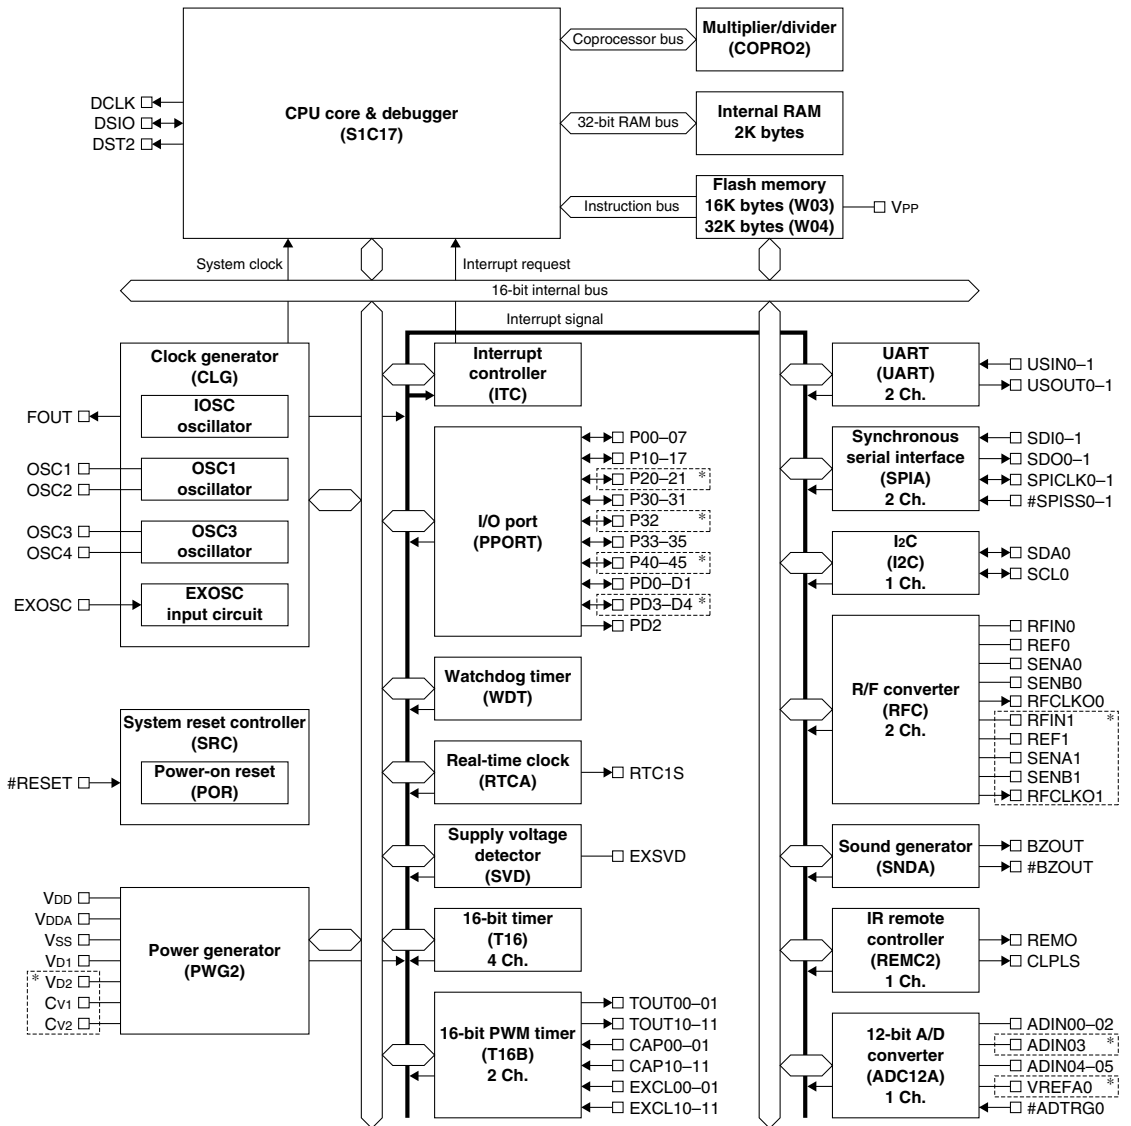

Model	S1C17W03	S1C17W04
<b>CPU</b>		
CPU core	Seiko Epson original 16-bit RISC CPU core S1C17	
Other	On-chip debugger	
<b>Embedded Flash memory</b>		
Capacity	16K bytes (for both instructions and data)	32K bytes (for both instructions and data)
Erase/program count	50 times (min.) * Programming by the debugging tool ICDmini	
Other	Security function to protect from reading/programming by ICDmini On-board programming function using ICDmini	
<b>Embedded RAM</b>		
Capacity	2K bytes	
<b>Clock generator (CLG)</b>		
System clock source	4 sources (IOSC/OSC1/OSC3/EXOSC)	
System clock frequency (operating frequency)	1.1 MHz (max.) $V_{DD} = 1.2$ to $1.6$ V 4.2 MHz (max.) $V_{DD} = 1.6$ to $3.6$ V	
IOSC oscillator circuit (boot clock source)	700 kHz (typ.) embedded oscillator 23 $\mu$ s (max.) starting time (time from cancelation of SLEEP state to vector table read by the CPU)	
OSC1 oscillator circuit	32.768 kHz (typ.) crystal oscillator Oscillation stop detection circuit included	
OSC3 oscillator circuit	4.2 MHz (max.) crystal/ceramic oscillator (48-pin package or chip) 250, 384, 500 kHz, 1, 2, and 4 MHz-switchable embedded oscillator 2.1 MHz (max.) CR oscillator (an external R is required) (48-pin package or chip)	
EXOSC clock input	4.2 MHz (max.) square or sine wave input	
Other	Configurable system clock division ratio Configurable system clock used at wake up from SLEEP state Operating clock frequency for the CPU and all peripheral circuits is selectable.	
<b>I/O port (PPORT)</b>		
Number of general-purpose I/O ports	Input/output port: 34 bits (max., 48-pin package or chip) 23 bits (max., 32-pin package) Output port: 1 bit (max.) Pins are shared with the peripheral I/O.	
Number of input interrupt ports	30 bits (max., 48-pin package or chip) 21 bits (max., 32-pin package)	
Number of ports that support universal port multiplexer (UPMUX)	24 bits (48-pin package or chip) 21 bits (32-pin package) A peripheral circuit I/O function selected via software can be assigned to each port.	
<b>Timers</b>		
Watchdog timer (WDT)	Generates NMI or watchdog timer reset.	
Real-time clock (RTCA)	128–1 Hz counter, second/minute/hour/day/day of the week/month/year counters Theoretical regulation function for 1-second correction Alarm and stopwatch functions	
16-bit timer (T16)	4 channels Generates the SPIA master clocks and the ADC12A operating clock/trigger signal.	
16-bit PWM timer (T16B)	2 channels Event counter/capture function PWM waveform generation function Number of PWM output or capture input ports: 2 ports/channel	
<b>Supply voltage detector (SVD)</b>		
Detection level	30 levels (1.2 to 3.6 V)	
Detection accuracy	$\pm 3$ %	
Other	Intermittent operation mode Generates an interrupt or reset according to the detection level evaluation.	

# 1 OVERVIEW

Model	S1C17W03	S1C17W04
<b>Serial interfaces</b>		
UART (UART)	2 channels Baud-rate generator included, IrDA1.0 supported	
Synchronous serial interface (SPIA)	2 channels 2 to 16-bit variable data length The 16-bit timer (T16) can be used for the baud-rate generator in master mode.	
I <sup>2</sup> C (I2C)	1 channel Baud-rate generator included	
<b>Sound generator (SNDA)</b>		
Buzzer output function	512 Hz to 16 kHz output frequencies One-shot output function	
Melody generation function	Pitch: 128 Hz to 16 kHz ≈ C3 to C6 Duration: 7 notes/rests (Half note/rest to thirty-second note/rest) Tempo: 16 tempos (30 to 480) Tie/slur may be specified.	
<b>IR remote controller (REMC2)</b>		
Number of transmitter channels	1 channel	
Other	EL lamp drive waveform can be generated for an application example.	
<b>R/F converter (RFC)</b>		
Conversion method	CR oscillation type with 24-bit counters	
Number of conversion channels	2 channels (48-pin package or chip) 1 channel (32-pin package) (Up to two sensors can be connected to each channel.)	
Supported sensors	DC-bias resistive sensors, AC-bias resistive sensors (Ch.0 only)	
<b>12-bit A/D converter (ADC12A)</b>		
Conversion method	Successive approximation type	
Resolution	12 bits	
Number of conversion channels	1 channel	
Number of analog signal inputs	6 ports/channel (48-pin package or chip) 5 ports/channel (32-pin package)	
<b>Multiplier/divider (COPRO2)</b>		
Arithmetic functions	16-bit × 16-bit multiplier 16-bit × 16-bit + 32-bit multiply and accumulation unit 32-bit ÷ 32-bit divider	
<b>Reset</b>		
#RESET pin	Reset when the reset pin is set to low.	
Power-on reset	Reset at power on.	
Key entry reset	Reset when the P00 to P01/P02/P03 keys are pressed simultaneously (can be enabled/disabled using a register).	
Watchdog timer reset	Reset when the watchdog timer overflows (can be enabled/disabled using a register).	
Supply voltage detector reset	Reset when the supply voltage detector detects the set voltage level (can be enabled/disabled using a register).	
<b>Interrupt</b>		
Non-maskable interrupt	4 systems (Reset, address misaligned interrupt, debug, NMI)	
Programmable interrupt	External interrupt: 1 system (8 levels) Internal interrupt: 20 systems (8 levels)	
<b>Power supply voltage</b>		
V <sub>DD</sub> operating voltage	1.2 to 3.6 V	
V <sub>DD</sub> operating voltage for Flash programming	1.8 to 3.6 V (V <sub>PP</sub> = 7.5 V external power supply is required.)	
V <sub>DD</sub> operating voltage for super economy mode	2.5 to 3.6 V (48-pin package or chip)	
V <sub>DDA</sub> analog operating voltage	1.2 to 3.6 V (Power supply for P3[5:0] and P4[5:4] ports)	
V <sub>DDA</sub> analog operating voltage for A/D conversion	1.8 to 3.6 V	
<b>Operating temperature</b>		
Operating temperature range	-40 to 85 °C	
<b>Current consumption (Typ. value)</b>		
SLEEP mode	0.15 μA I <sub>OSC</sub> = OFF, OSC1 = OFF, OSC3 = OFF	
HALT mode	0.5 μA OSC1 = 32 kHz, RTC = ON 0.3 μA (48-pin package or chip) OSC1 = 32 kHz, RTC = ON, super economy mode	
RUN mode	8 μA OSC1 = 32 kHz, RTC = ON, CPU = OSC1 4 μA (48-pin package or chip) OSC1 = 32 kHz, RTC = ON, CPU = OSC1, super economy mode 250 μA OSC3 = 1 MHz (ceramic oscillator), OSC1 = 32 kHz, RTC = ON, CPU = OSC3	
<b>Shipping form</b>

## 1.3.3 Pin Descriptions

### Symbol meanings

Assigned signal: The signal listed at the top of each pin is assigned in the initial state. The pin function must be switched via software to assign another signal (see the “I/O Ports” chapter).

I/O:            I            = Input  
                   O            = Output  
                   I/O        = Input/output  
                   P            = Power supply  
                   A            = Analog signal  
                   Hi-Z        = High impedance state

Initial state: I (Pull-up) = Input with pulled up  
 I (Pull-down) = Input with pulled down  
 Hi-Z        = High impedance state  
 O (H)      = High level output  
 O (L)      = Low level output

Tolerant fail-safe structure:  
 ✓            = Over voltage tolerant fail-safe type I/O cell included (see the “I/O Ports” chapter)

### Universal port multiplexer (UPMUX)

The universal port multiplexer (UPMUX) allows software to select the peripheral circuit input/output function to be assigned to each pin from those listed below.

Table 1.3.3.2 Peripheral Circuit Input/output Function Selectable by UPMUX

Peripheral circuit	Signal to be assigned	I/O	Channel number <i>n</i>	Function

**Note:** Do not assign a function to two or more pins simultaneously.

# 2 Power Supply, Reset, and Clocks

The power supply, reset, and clocks in this IC are managed by the embedded power generator, system reset controller, and clock generator, respectively.

## 2.1 Power Generator (PWG2)

### 2.1.1 Overview

PWG2 is the power generator that controls the internal power supply system to drive this IC with stability and low power. The main features of PWG2 are outlined below.

- High-efficiency DC-DC converter for driving internal circuits
- Supports four operating modes including automatic transition to power-saving operations (normal mode, economy mode, automatic mode, and super economy mode).
- A few internal circuits are driven with  $V_{DDA}$ , this makes it possible to operate them with a voltage different from  $V_{DD}$ .

Figure 2.1.1.1 shows the PWG2 configuration.

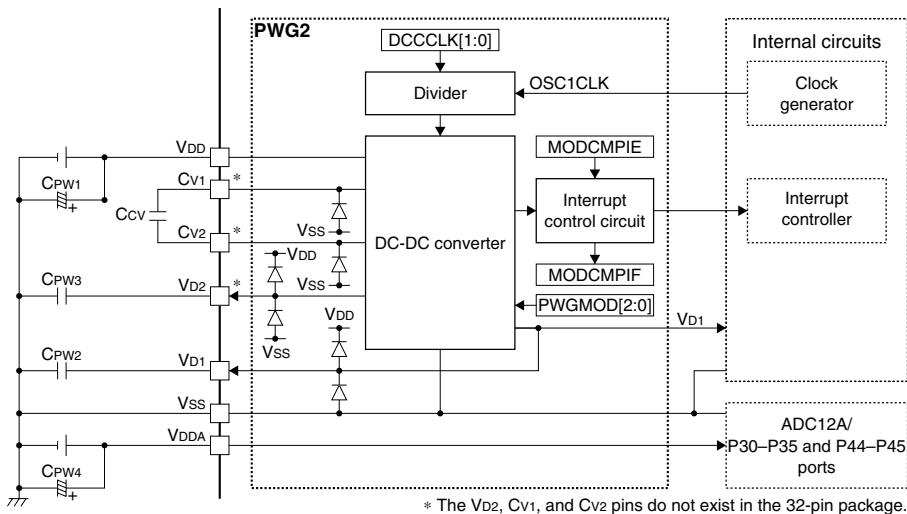

Figure 2.1.1.1 PWG2 Configuration

**Note:** The 32-pin package model cannot be placed into super economy mode, as it does not have the  $V_{D2}$ ,  $CV_1$ , and  $CV_2$  pins.

### 2.1.2 Pins

Table 2.1.2.1 lists the PWG2 pins.

Table 2.1.2.1 List of PWG2 Pins

Pin name	I/O	Initial status	Function
$V_{DD}$	P	–	Power supply (+)
$V_{DDA}$	P	–	Analog power supply (+)
$V_{SS}$	P	–	GND
$V_{D1}$	A	–	DC-DC converter output pin
$V_{D2}$	A	–	DC-DC converter stabilization capacitor connect pin
$CV_1, CV_2$	A	–	DC-DC converter charge pump capacitor connect pins

For the  $V_{DD}$  and  $V_{DDA}$  operating voltages and recommended external parts, refer to “Recommended Operating Conditions, Power supply voltage  $V_{DD}$  and Analog power supply voltage  $V_{DDA}$ ” in the “Electrical Characteristics” chapter and the “Basic External Connection Diagram” chapter, respectively.

- Notes:**
- Be sure to avoid using the  $V_{D1}$  and  $V_{D2}$  pin outputs for driving external circuits.
  - The  $V_{DDA}$  pin must be connected to a power supply (to  $V_{DD}$  if not used).

## 2.1.3 Operations

PWG2 provides four operating modes listed in Table 2.1.3.1.

Table 2.1.3.1 PWG2 Operating Mode

Operating mode	Power consumption	Conditions of use
Normal mode	High ↑	None
Automatic mode		None
Economy mode	↓ Low	All the clock sources except for OSC1 are halted (RUN, HALT, or SLEEP mode) or all the clock sources are halted (SLEEP mode).
Super economy mode		1) V <sub>DD</sub> meets the voltage requirement. *1 2) OSC1 is operating with stability and all other clock sources are halted (when OSC1 is not configured to halt in RUN, HALT, or SLEEP mode).

\*1 For the V<sub>DD</sub> voltage range to set super economy mode, refer to “Recommended Operating Conditions, Power supply voltage V<sub>DD</sub>” in the “Electrical Characteristics” chapter.

### Normal mode

Using this mode results in the highest power consumption within the four operating modes, however, it provides high-stability operations without being affected by voltage fluctuations.

#### Switching to normal mode from another mode (economy mode)

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Set the PWGCTL.PWGMOD[2:0] bits to 0x2. (Set to normal mode)
3. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

### Economy mode

PWG2 performs power-saving operations. Power consumption can be reduced in comparison with normal mode. However, this mode can be set only when the system is under light load conditions (see “Condition of use” for economy mode in Table 2.1.3.1) because of its lack of V<sub>D1</sub> drive capability. Therefore, economy mode does not allow use of high-speed clocks (IOSC, OSC3, and EXOSC).

#### Switching to economy mode from another mode (normal mode)

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Check to see if the OSC1 oscillation has stabilized (see “Oscillation start procedure for the OSC1 oscillator circuit” in Section 2.3.4.).
3. Stop the high-speed clock sources.
4. Set the PWGCTL.PWGMOD[2:0] bits to 0x3. (Set to economy mode)
5. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

**Note:** Be sure to avoid switching to economy mode while a high-speed clock source is operating, as it may cause a malfunction.

### Automatic mode

In this mode, the hardware automatically switches between normal mode and economy mode as described above. Use PWG2 in automatic mode when no special control is required.

#### Switching to automatic mode from another mode

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Set the PWGCTL.PWGMOD[2:0] bits to 0x0. (Set to automatic mode)
3. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

The following shows the conditions for the hardware to switch between normal mode and economy mode and its operations:

1. When all the clock sources except for OSC1 are stopped in normal mode  
After a lapse of 1 ms from stop of the clock source, the hardware switches from normal mode to economy mode and sets the PWGINTF.MODCMPPIF bit to 1.
2. When a clock source other than OSC1 is started in economy mode  
The hardware switches to normal mode at the same time the clock source is started.

3. When the `slp` instruction is executed in normal mode (all the clocks are configured to stop during SLEEP)  
The hardware switches to economy mode at the same time the CPU enters SLEEP mode. The `PWGINTE.MODCMPIF` bit is not set.
4. When the `slp` instruction is executed in normal mode (only `OSC1` operates during SLEEP)  
After a lapse of 1 ms from transition to SLEEP mode, the hardware switches from normal mode to economy mode and sets the `PWGINTE.MODCMPIF` bit to 1.
5. When the CPU wakes up from SLEEP state  
At the same time the CPU enters RUN mode, the hardware switches to economy mode when `OSC1` only is operating or to normal mode in other conditions.

For the `PWGINTE.MODCMPIF` bit set conditions, refer to “Interrupts.”

### Super economy mode

Super economy mode uses a charge pump to generate  $V_{D1}$  that is generated by the linear regulator in the three operating modes described above. This achieves more power-saving operation in comparison with economy mode. However, the charge pump operation requires a  $V_{DD}$  voltage that exceeds the prescribed value. Furthermore, super economy mode does not allow use of high-speed clocks (`IOSC`, `OSC3`, and `EXOSC`) because of its lack of drive capability.

#### Switching to super economy mode from another mode (automatic mode)

1. Check to see if  $V_{DD}$  meets the requirement using the supply voltage detector.
2. Write 0x0096 to the `MSCPROT.PROT[15:0]` bits. (Remove system protection)
3. Check to see if the `OSC1` oscillation has stabilized (see “Oscillation start procedure for the `OSC1` oscillator circuit” in Section 2.3.4.).
4. Stop the high-speed clock sources.
5. Set the `PWGTIM.DCCCLK[1:0]` bits (first time only). (Set charge pump operating clock division ratio)
6. Set the `PWGCTL.PWGMOD[2:0]` bits to 0x5. (Set to super economy mode)
7. Write a value other than 0x0096 to the `MSCPROT.PROT[15:0]` bits. (Set system protection)

- Notes:**
- Be sure to avoid setting to super economy mode under the conditions shown below, as it may cause a runaway CPU.
    1.  $V_{DD}$  does not meet the requirement for super economy mode.
    2. A clock source other than `OSC1` is operating.
    3. `OSC1` clock is not stabilized.
  - The charge pump operates with the `OSC1` clock. Therefore, to put the CPU into SLEEP state in super economy mode, the clock sources must be configured so that `OSC1` only will operate in SLEEP mode (`CLGOSC.OSC1SLPC` bit = 0 and other `CLGOSC.***SLPC` bits = 1).

#### Switching to automatic mode/economy mode from super economy mode

1. Write 0x0096 to the `MSCPROT.PROT[15:0]` bits. (Remove system protection)
2. Set the `PWGCTL.PWGMOD[2:0]` bits to 0x0. (Set to automatic mode)  
Or set the `PWGCTL.PWGMOD[2:0]` bits to 0x3. (Set to economy mode)
3. Write a value other than 0x0096 to the `MSCPROT.PROT[15:0]` bits. (Set system protection)
4. Check to see if the `PWGINTE.MODCMPIF` bit = 1 (mode transition completed).

For the `PWGINTE.MODCMPIF` bit set conditions, refer to “Interrupts.”

- Notes:**
- Be sure to avoid switching to normal mode directly from super economy mode, as it may cause a malfunction. When using a high-speed clock, first switch to automatic mode before starting the clock source.
  - The `PWGINTE.MODCMPIF` bit is set to 1 after a lapse of 10 ms from the switching operation from super economy mode to automatic mode (or economy mode). Do not perform heavy-load operations, such as starting a high-speed clock source, before the `PWGINTE.MODCMPIF` bit is set to 1, as it may cause a malfunction.

## 2.2 System Reset Controller (SRC)

### 2.2.1 Overview

SRC is the system reset controller that resets the internal circuits according to the requests from the reset sources to archive steady IC operations. The main features of SRC are outlined below.

- Embedded reset hold circuit maintains reset state to boot the system safely while the internal power supply is unstable after power on or the oscillation frequency is unstable after the clock source is initiated.
- Supports reset requests from multiple reset sources.
  - #RESET pin
  - POR
  - Key-entry reset
  - Watchdog timer reset
  - Supply voltage detector reset
  - Peripheral circuit software reset (supports some peripheral circuits only)
- The CPU registers and peripheral circuit control bits will be reset with an appropriate initialization condition according to changes in status.

Figure 2.2.1.1 shows the SRC configuration.

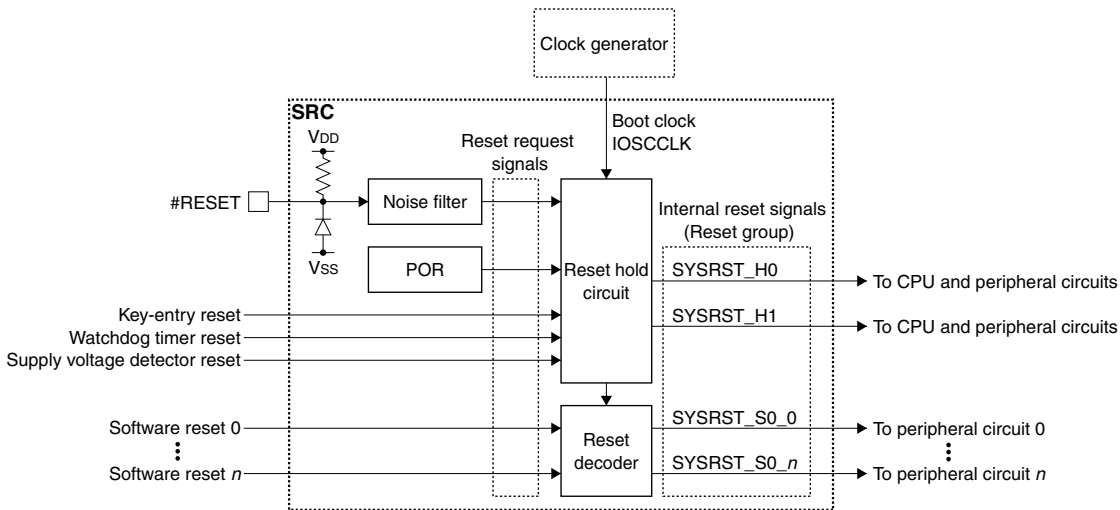

Figure 2.2.1.1 SRC Configuration

### 2.2.2 Input Pin

Table 2.2.2.1 shows the SRC pin.

Table 2.2.2.1 SRC Pin

Pin name	I/O	Initial status	Function
#RESET	I	I (Pull-up)	Reset input

The #RESET pin is connected to the noise filter that removes pulses not conforming to the requirements. An internal pull-up resistor is connected to the #RESET pin, so the pin can be left open. For the #RESET pin characteristics, refer to “#RESET pin characteristics” in the “Electrical Characteristics” chapter.

### 2.2.3 Reset Sources

The reset source refers to causes that request system initialization. The following shows the reset sources.

#### #RESET pin

Inputting a reset signal with a certain low level period to the #RESET pin issues a reset request.

## POR

POR (Power On Reset) issues a reset request when the rise of  $V_{DD}$  is detected. Reset requests from this circuit ensure that the system will be reset properly when the power is turned on. Figure 2.2.3.1 shows an example of POR internal reset operation according to variations in  $V_{DD}$ .

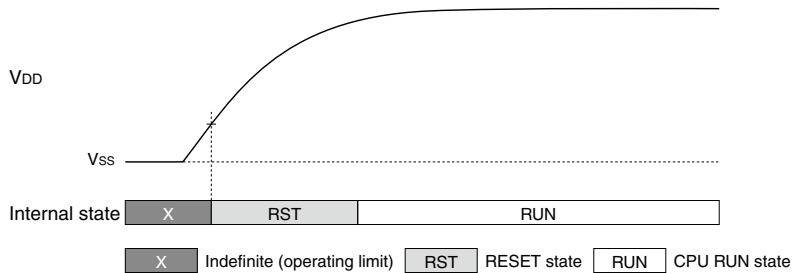

Figure 2.2.3.1 Example of Internal Reset by POR

For the POR electrical specifications, refer to “POR characteristics” in the “Electrical Characteristics” chapter.

### Key-entry reset

Inputting a low level signal of a certain period to the I/O port pins configured to a reset input issues a reset request. This function must be enabled using an I/O port register. For more information, refer to the “I/O Ports” chapter.

### Watchdog timer reset

Setting the watchdog timer into reset mode will issue a reset request when the counter overflows. This helps return the runaway CPU to a normal operating state. For more information, refer to the “Watchdog timer” chapter.

### Supply voltage detector reset

By enabling the low power supply voltage detection reset function, the supply voltage detector will issue a reset request when a drop in the power supply voltage is detected. This makes it possible to put the system into reset state if the IC must be stopped under a low voltage condition. For more information, refer to the “Supply Voltage Detector” chapter.

### Peripheral circuit software reset

Some peripheral circuits provide a control bit for software reset (MODEN or SFTRST). Setting this bit initializes the peripheral circuit control bits. Note, however, that the software reset operations depend on the peripheral circuit. For more information, refer to “Control Registers” in each peripheral circuit chapter.

**Note:** The MODEN bit of some peripheral circuits does not issue software reset.

## 2.2.4 Initialization Conditions (Reset Groups)

A different initialization condition is set for the CPU registers and peripheral circuit control bits, individually. The reset group refers to an initialization condition. Initialization is performed when a reset source included in a reset group issues a reset request. Table 2.2.4.1 lists the reset groups. For the reset group to initialize the registers and control bits, refer to the “CPU and Debugger” chapter or “Control Registers” in each peripheral circuit chapter.

Table 2.2.4.1 List of Reset Groups

Reset group	Reset source	Reset cancelation timing
H0	#RESET pin POR Key-entry reset Supply voltage detector reset Watchdog timer reset	Reset state is maintained for the reset hold time $t_{RSTR}$ after the reset request is canceled.
H1	#RESET pin POR	
S0	Peripheral circuit software reset (MODEN and SFTRST bits. The software reset operations depend on the peripheral circuit.	Reset state is canceled immediately after the reset request is canceled.

## 2.3 Clock Generator (CLG)

### 2.3.1 Overview

CLG is the clock generator that controls the clock sources and manages clock supply to the CPU and the peripheral circuits. The main features of CLG are outlined below.

- Supports multiple clock sources.
  - IOSC oscillator circuit that oscillates with a fast startup and no external parts required
  - High-precision and low-power OSC1 oscillator circuit that uses a 32.768 kHz crystal resonator
  - OSC3 oscillator circuit in which the oscillator type can be specified from crystal/ceramic oscillator (an external resonator is required), CR oscillator (an external R is required), and internal oscillator
  - EXOSC clock input circuit that allows input of square wave and sine wave clock signals
- The system clock (SYSCLK), which is used as the operating clock for the CPU and bus, and the peripheral circuit operating clocks can be configured individually by selecting the suitable clock source and division ratio.
- IOSCCLK output from the IOSC oscillator circuit is used as the boot clock for fast booting.
- Controls the oscillator and clock input circuits to enable/disable according to the operating mode, RUN or SLEEP mode.
- Provides a flexible system clock switching function at SLEEP mode cancellation.
  - The clock sources to be stopped in SLEEP mode can be selected.
  - SYSCLK to be used at SLEEP mode cancellation can be selected from all clock sources.
  - The oscillator and clock input circuit on/off state can be maintained or changed at SLEEP mode cancellation.
- Provides the FOUT function to output an internal clock for driving external ICs or for monitoring the internal state.

Figure 2.3.1.1 shows the CLG configuration.

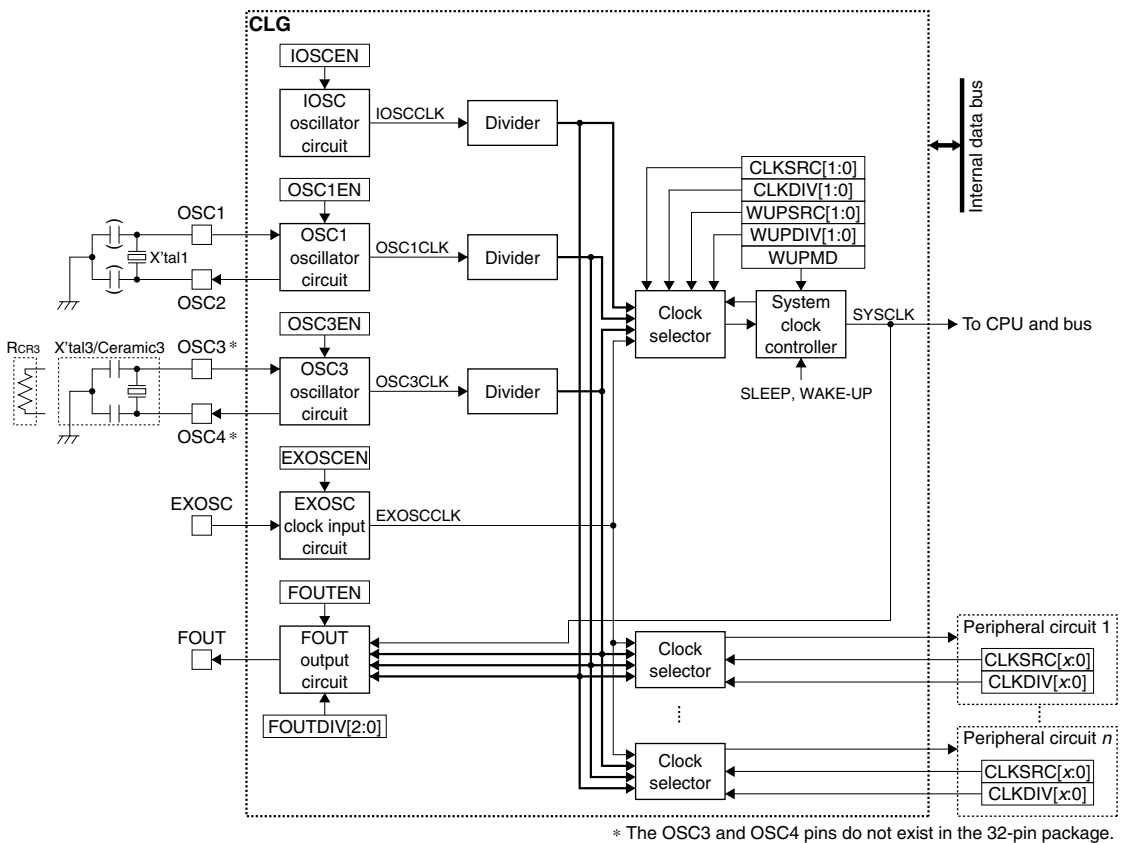

Figure 2.3.1.1 CLG Configuration

## 2.3.2 Input/Output Pins

Table 2.3.2.1 lists the CLG pins.

Table 2.3.2.1 List of CLG Pins

Pin name	I/O*	Initial status*	Function
OSC1	A	–	OSC1 oscillator circuit input
OSC2	A	–	OSC1 oscillator circuit output
OSC3	A	–	OSC3 oscillator circuit input
OSC4	A	–	OSC3 oscillator circuit output
EXOSC	I	I	EXOSC clock input
FOUT	O	O (L)	FOUT clock output

\* Indicates the status when the pin is configured for CLG.

If the port is shared with the CLG input/output function and other functions, the CLG function must be assigned to the port. For more information, refer to the “I/O Ports” chapter.

## 2.3.3 Clock Sources

### IOSC oscillator circuit

The IOSC oscillator circuit features a fast startup and no external parts are required for oscillating. Figure 2.3.3.1 shows the configuration of the IOSC oscillator circuit.

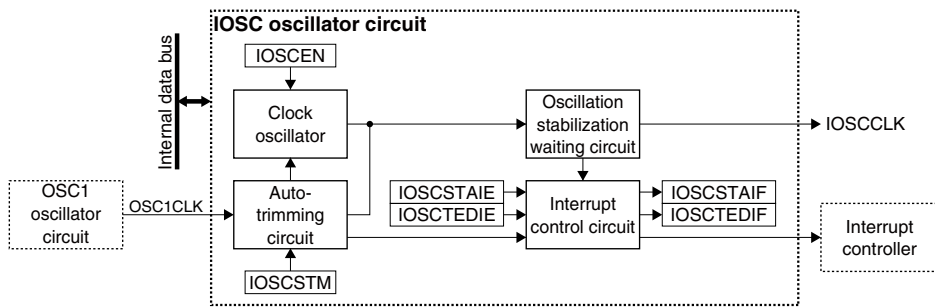

Figure 2.3.3.1 IOSC Oscillator Circuit Configuration

The IOSC oscillator circuit output clock IOSCCLK is used as SYSCLK at booting. The IOSC oscillator circuit is equipped with an auto-trimming function that automatically adjusts the frequency. This helps reduce frequency deviation due to unevenness in manufacturing quality, temperature, and changes in voltage. For more information on the auto-trimming function and the oscillation characteristics, refer to “IOSC oscillation auto-trimming function” in this chapter and “IOSC oscillator circuit characteristics” in the “Electrical Characteristics” chapter, respectively.

### OSC1 oscillator circuit

The OSC1 oscillator circuit is a high-precision and low-power oscillator circuit that uses a 32.768 kHz crystal resonator. Figure 2.3.3.2 shows the configuration of the OSC1 oscillator circuit.

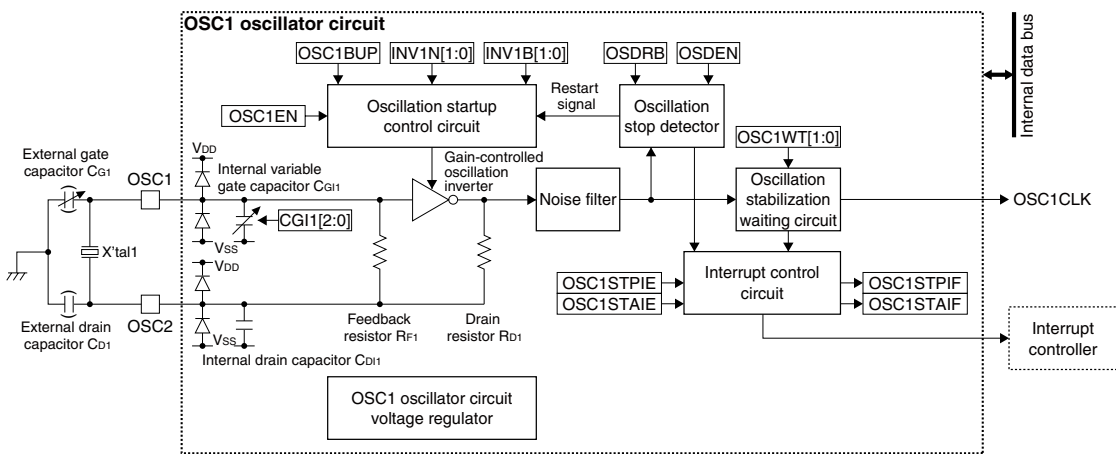

Figure 2.3.3.2 OSC1 Oscillator Circuit Configuration

This oscillator circuit includes a gain-controlled oscillation inverter and a variable gate capacitor allowing use of various crystal resonators with ranges from cylinder type through surface-mount type. The oscillator circuit also includes a feedback resistor and a drain resistor, so no external parts are required except for a crystal resonator. The embedded oscillation stop detector, which detects oscillation stop and restarts the oscillator, allows the system to operate in safety under adverse environments that may stop the oscillation. The oscillation startup control circuit operates for a set period of time after the oscillation is enabled to assist the oscillator in initiating, this makes it possible to use a low-power resonator that is difficult to start up. For the recommended parts and the oscillation characteristics, refer to the “Basic External Connection Diagram” chapter and “OSC1 oscillator circuit characteristics” in the “Electrical Characteristics” chapter, respectively.

**Note:** Depending on the circuit board or the crystal resonator type used, an external gate capacitor  $C_{G1}$  and a drain capacitor  $C_{D1}$  may be required.

### OSC3 oscillator circuit

The OSC3 oscillator circuit is a high-speed oscillator circuit that allows software to select the oscillator type from three types shown below. Figure 2.3.3.3 shows the configuration of the OSC3 oscillator circuit.

#### Crystal/ceramic oscillator

This oscillator circuit includes a feedback resistor and a drain resistor, so no external part is required except for a crystal/ceramic resonator. The embedded gain-controlled inverter allows selection of the resonator from a wide frequency range.

#### CR oscillator

This oscillator circuit includes an oscillation capacitor ( $C_{CR3}$ ), and the frequency can be adjusted by the resistor ( $R_{CR3}$ ). No external part is required except for  $R_{CR3}$ .

#### Internal oscillator

This oscillator circuit operates without any external parts, and its oscillation frequency can be selected via software.

- Notes:**
- The maximum value of the OSC3 oscillator circuit oscillation frequency  $f_{osc3}$  depends on the supply voltage  $V_{DD}$  value. For the oscillation frequency range, refer to “Recommended Operating Conditions” in the “Electrical Characteristics” chapter.
  - When the CR oscillator is selected, the changes in the signals output from the I/O pins adjacent to the OSC3 and OSC4 pins may affect the oscillation frequency.
  - When the internal oscillator is selected, be sure to avoid using the pins to which OSC3 and OSC4 are assigned as input pins, as it may affect the oscillation frequency.

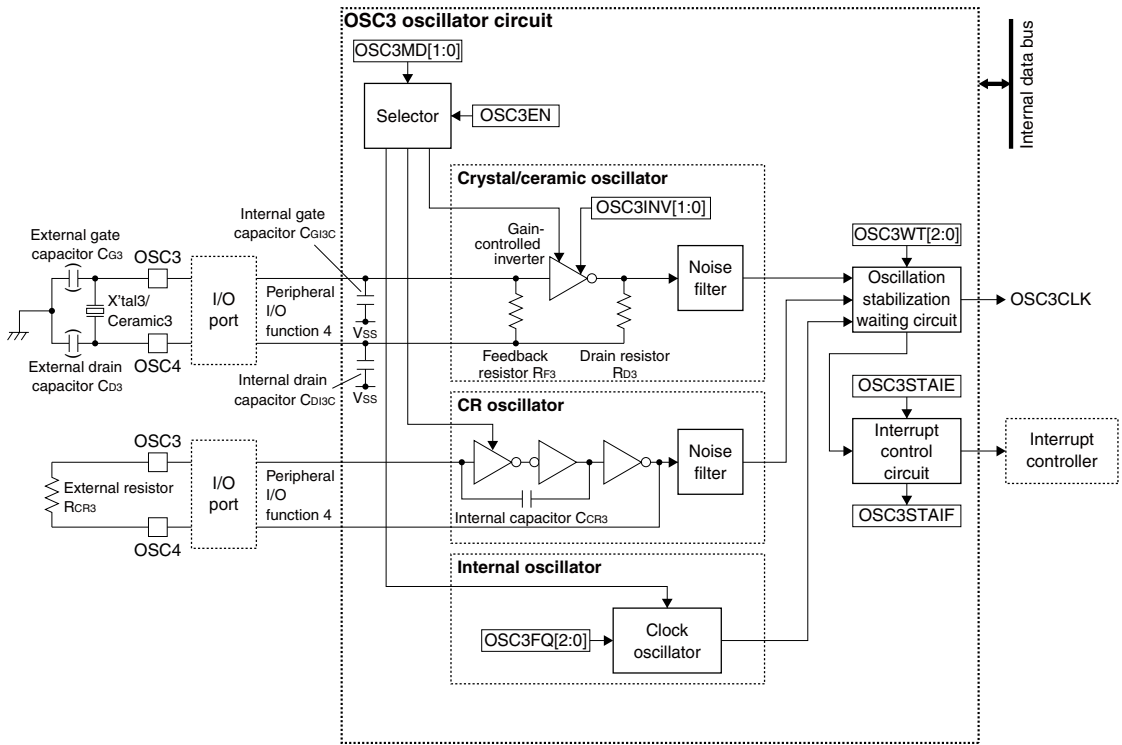

Figure 2.3.3.3 OSC3 Oscillator Circuit Configuration

For the recommended parts and the oscillation characteristics, refer to the “Basic External Connection Diagram” chapter and the “Electrical Characteristics” chapter, respectively.

### EXOSC clock input

EXOSC is an external clock input circuit that supports square wave and sine wave clocks. Figure 2.3.3.4 shows the configuration of the EXOSC clock input circuit.

Figure 2.3.3.4 EXOSC Clock Input Circuit

EXOSC has no oscillation stabilization waiting circuit included, therefore, it must be enabled when a stabilized clock is being supplied. For the input clock characteristics, refer to “EXOSC external clock input characteristics” in the “Electrical Characteristics” chapter.

## 2.3.4 Operations

### Oscillation start time and oscillation stabilization waiting time

The oscillation start time refers to the time after the oscillator circuit is enabled until the oscillation signal is actually sent to the internal circuits. The oscillation stabilization waiting time refers to the time it takes the clock to stabilize after the oscillation starts. To avoid malfunctions of the internal circuits due to an unstable clock during this period, the oscillator circuit includes an oscillation stabilization waiting circuit that can disable supplying the clock to the system until the designated time has elapsed. Figure 2.3.4.1 shows the relationship between the oscillation start time and the oscillation stabilization waiting time.

Figure 2.3.4.1 Oscillation Start Time and Oscillation Stabilization Waiting Time

The oscillation stabilization waiting times for the OSC1 and OSC3 oscillator circuits can be set using the CLGOSC1.OSC1WT[1:0] bits and CLGOSC3.OSC3WT[2:0] bits, respectively. To check whether the oscillation stabilization waiting time is set properly and the clock is stabilized immediately after the oscillation starts or not, monitor the oscillation clock using the FOUT output function. The oscillation stabilization waiting time for the IOSC oscillator circuit is fixed at 16 IOSCLK clocks. The oscillation stabilization waiting time for the OSC3 oscillator circuit should be set to 1,024 OSC3CLK clocks or more when crystal/ceramic oscillator is selected, or four OSC3CLK clocks or more when CR oscillator or internal oscillator is selected.

When the oscillation stabilization waiting operation has completed, the oscillator circuit sets the oscillation stabilization waiting completion flag and starts clock supply to the internal circuits.

**Note:** The oscillation stabilization waiting time is always expended at start of oscillation even if the oscillation stabilization waiting completion flag has not be cleared to 0.

When the oscillation startup control circuit in the OSC1 oscillator circuit is enabled by setting the CLGOSC1.OSC1BUP bit to 1, it uses the high-gain oscillation inverter for a set period of time (startup boosting operation) after the oscillator circuit is enabled (by setting the CLGOSC.OSC1EN bit to 1) to reduce oscillation start time. Note, however, that the oscillation operation may become unstable if there is a large gain differential between normal operation and startup boosting operation. Furthermore, the oscillation start time being actually reduced depends on the characteristics of the resonator used. Figure 2.3.4.2 shows an operation example when the oscillation startup control circuit is used.

(1) CLGOSC1.OSC1BUP bit = 0 (startup boosting operation disabled)

(2) CLGOSC1.OSC1BUP bit = 1 (startup boosting operation enabled)

Figure 2.3.4.2 Operation Example when the Oscillation Startup Control Circuit is Used

### Oscillation start procedure for the IOSC oscillator circuit

Follow the procedure shown below to start oscillation of the IOSC oscillator circuit.

1. Write 1 to the CLGINTF.IOSCSTAIF bit. (Clear interrupt flag)
2. Write 1 to the CLGINTE.IOSCSTAIE bit. (Enable interrupt)
3. Write 1 to the CLGOSC.IOSCEN bit. (Start oscillation)
4. IOSCCLK can be used if the CLGINTF.IOSCSTAIF bit = 1 after an interrupt occurs.

### Oscillation start procedure for the OSC1 oscillator circuit

Follow the procedure shown below to start oscillation of the OSC1 oscillator circuit.

1. Write 1 to the CLGINTF.OSC1STAIF bit. (Clear interrupt flag)
2. Write 1 to the CLGINTE.OSC1STAIE bit. (Enable interrupt)
3. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
4. Configure the following CLGOSC1 register bits according to the resonator used:
  - CLGOSC1.INV1N[1:0] bits (Set oscillation inverter gain)
  - CLGOSC1.CGI1[2:0] bits (Set internal gate capacitor)
  - CLGOSC1.OSC1WT[1:0] bits (Set oscillation stabilization waiting time)

In addition to the above, configure the following bits when using the oscillation startup control circuit (see Figure 2.3.4.2):

- CLGOSC1.INV1B[1:0] bits (Set oscillation inverter gain for startup boosting period)
  - Set the CLGOSC1.OSC1BUP bit to 1. (Enable oscillation startup control circuit)
5. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)
  6. Write 1 to the CLGOSC.OSC1EN bit. (Start oscillation)
  7. OSC1CLK can be used if the CLGINTF.OSC1STAIF bit = 1 after an interrupt occurs.

The setting values of the CLGOSC1.INV1N[1:0], CLGOSC1.CGI1[2:0], CLGOSC1.OSC1WT[1:0], and CLGOSC1.INV1B[1:0] bits should be determined after performing evaluation using the populated circuit board.

### Oscillation start procedure for the OSC3 oscillator circuit

Follow the procedure shown below to start oscillation of the OSC3 oscillator circuit.

1. Write 1 to the CLGINTF.OSC3STAIF bit. (Clear interrupt flag)
2. Write 1 to the CLGINTE.OSC3STAIE bit. (Enable interrupt)
3. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
4. Configure the following CLGOSC3 register bits.
  - CLGOSC3.OSC3MD[1:0] bits (Select oscillator type)
  - CLGOSC3.OSC3WT[2:0] bits (Set oscillation stabilization waiting time)

In addition to the above, configure the following bits when using the crystal/ceramic oscillator:

- CLGOSC3.OSC3INV[1:0] bits (Set oscillation inverter gain)

Configure the following bits when using the internal oscillator:

- CLGOSC3.OSC3FQ[2:0] bits (Select oscillation frequency)

5. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)
6. When using the crystal/ceramic or CR oscillator, assign the OSC3 oscillator input/output functions to the ports. (Refer to the “I/O Ports” chapter.)
7. Write 1 to the CLGOSC.OSC3EN bit. (Start oscillation)
8. OSC3CLK can be used if the CLGINTF.OSC3STAIF bit = 1 after an interrupt occurs.

The setting values of the CLGOSC3.OSC3INV[1:0] and CLGOSC3.OSC3WT[2:0] bits should be determined after performing evaluation using the populated circuit board.

**Note:** Make sure the CLGOSC.OSC3EN bit is set to 0 (while the OSC3 oscillation is halted) when switching the oscillator within three types.

### System clock switching

The CPU boots using IOSCCCLK as SYSCLK. After booting, the clock source of SYSCLK can be switched according to the processing speed required. The SYSCLK frequency can also be set by selecting the clock source division ratio, this makes it possible to run the CPU at the most suitable performance for the process to be executed. The CLGSCLK.CLKSRC[1:0] and CLGSCLK.CLKDIV[1:0] bits are used for this control.

The CLGSCLK register bits are protected against writings by the system protect function, therefore, the system protection must be removed by writing 0x0096 to the MSCPROT.PROT[15:0] bits before the register setting can be altered. For the transition between the operating modes including the system clock switching, refer to “Operating Mode.”

### Clock control in SLEEP mode

The CPU enters SLEEP mode when it executes the slp instruction. Whether the clock sources being operated are stopped or not at this point can be selected in each source individually. This allows the CPU to fast switch between SLEEP mode and RUN mode, and the peripheral circuits to continue operating without disabling the clock in SLEEP mode. The CLGOSC.IOSCSLPC, CLGOSC.OSC1SLPC, CLGOSC.OSC3SLPC, and CLGOSC.EXOSCSLPC bits are used for this control. Figure 2.3.4.3 shows a control example.

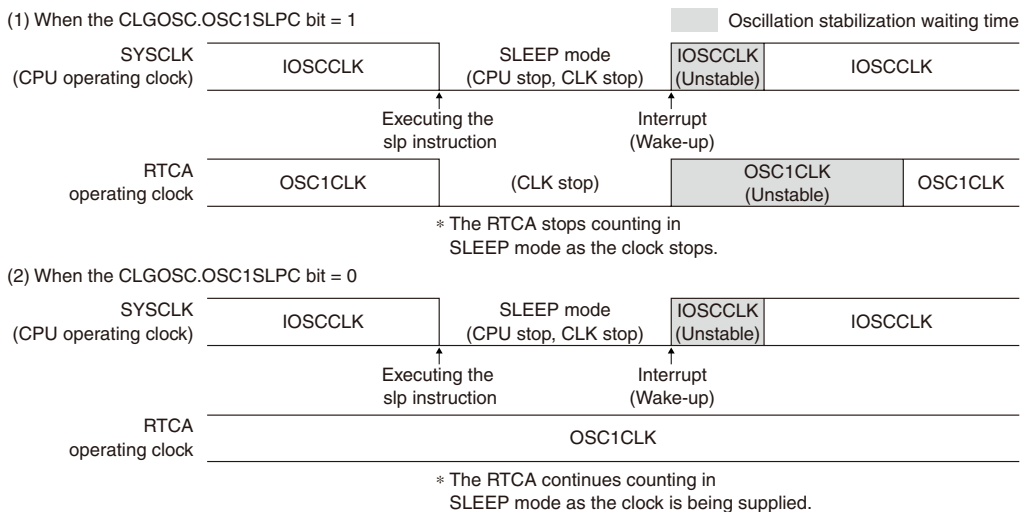

Figure 2.3.4.3 Clock Control Example in SLEEP Mode

The SYSCLK condition (clock source and division ratio) at wake-up from SLEEP mode to RUN mode can also be configured. This allows flexible clock control according to the wake-up process. Configure the clock using the CLGSCLK.WUPSRC[1:0] and CLGSCLK.WUPDIV[1:0] bits, and write 1 to the CLGSCLK.WUPMD bit to enable this function.

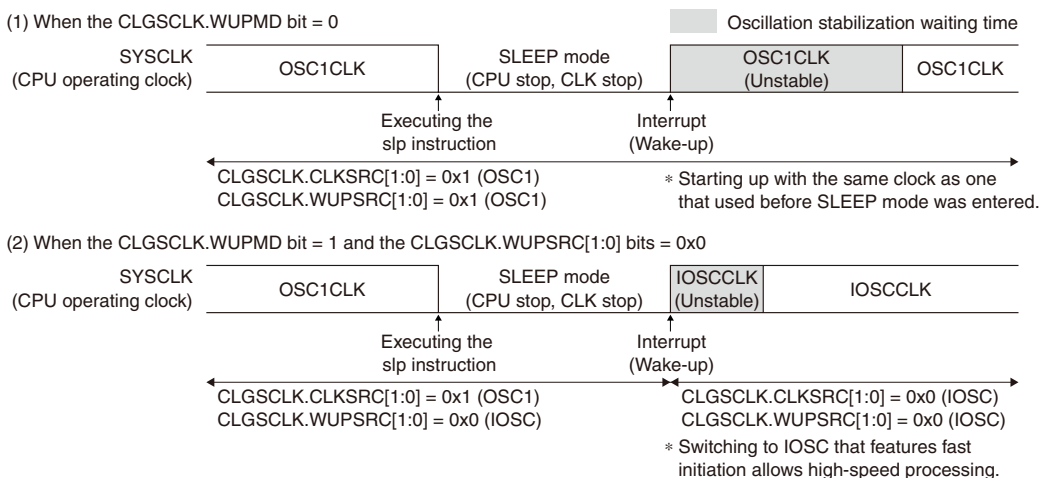

Figure 2.3.4.4 Clock Control Example at SLEEP Cancellation

### Clock external output (FOUT)

The FOUT pin can output the clock generated by a clock source or its divided clock to outside the IC. This allows monitoring the oscillation frequency of the oscillator circuit or supplying an operating clock to external ICs. Follow the procedure shown below to start clock external output.

1. Assign the FOUT function to the port. (Refer to the “I/O Ports” chapter.)
2. Configure the following CLGFOUT register bits:
  - CLGFOUT.FOUTSRC[1:0] bits (Select clock source)
  - CLGFOUT.FOUTDIV[2:0] bits (Set clock division ratio)
  - Set the CLGFOUT.FOUTEN bit to 1. (Enable clock external output)

### IOSC oscillation auto-trimming function

The auto-trimming function adjusts the IOSCCLK clock frequency by trimming the clock with reference to the high precision OSC1CLK clock generated by the OSC1 oscillator circuit. Follow the procedure shown below to enable the auto-trimming function.

1. After enabling the OSC1 oscillation, check if the stabilized clock is supplied (CLGINTF.OSC1STAIF bit = 1).
2. After enabling the IOSC oscillation, check if the stabilized clock is supplied (CLGINTF.IOSCSTAIF bit = 1).
3. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
4. If the SYSCLK clock source is IOSC, set the CLGSCLK.CLKSRC[1:0] bits to a value other than 0x0 (IOSC).
5. Write 1 to the CLGINTF.IOSCTEDIF bit. (Clear interrupt flag)
6. Write 1 to the CLGINTF.IOSCTEDIE bit. (Enable interrupt)
7. Write 1 to the CLGIOSC.IOSCSTM bit. (Enable IOSC oscillation auto-trimming)
8. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)
9. The trimmed IOSCCLK can be used if the CLGINTF.IOSCTEDIF bit = 1 after an interrupt occurs.

After the trimming operation has completed, the CLGIOSC.IOSCSTM bit automatically reverts to 0. Although the trimming time depends on the temperature, an average of several 10 ms is required. When IOSCCLK is being used as the system clock or a peripheral circuit clock, do not use the auto-trimming function.

### OSC1 oscillation stop detection function

The oscillation stop detection function restarts the OSC1 oscillator circuit when it detects oscillation stop under adverse environments that may stop the oscillation. Follow the procedure shown below to enable the oscillation stop detection function.

1. After enabling the OSC1 oscillation, check if the stabilized clock is supplied (CLGINTF.OSC1STAIF bit = 1).
2. Write 1 to the CLGINTF.OSC1STPIF bit. (Clear interrupt flag)
3. Write 1 to the CLGINTF.OSC1STPIE bit. (Enable interrupt)
4. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
5. Set the following CLGOSC1 register bits:
  - Set the CLGOSC1.OSDRB bit to 1. (Enable OSC1 restart function)
  - Set the CLGOSC1.OSDEN bit to 1. (Enable oscillation stop detection function)
6. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)
7. The OSC1 oscillation stops if the CLGINTF.OSC1STPIF bit = 1 after an interrupt occurs. If the CLGOSC1.OSDRB bit = 1, the hardware restarts the OSC1 oscillator circuit.

**Note:** Enabling the oscillation stop detection function increase the oscillation stop detector current (I<sub>OSD1</sub>).

## 2.4 Operating Mode

### 2.4.1 Initial Boot Sequence

Figure 2.4.1.1 shows the initial boot sequence after power is turned on.

Figure 2.4.1.1 Initial Boot Sequence

**Note:** The reset cancellation time at power-on varies according to the power rise time and reset request cancellation time.

For the reset hold time  $t_{RSTR}$ , refer to “Reset hold circuit characteristics” in the “Electrical Characteristics” chapter.

### 2.4.2 Transition between Operating Modes

State transitions between operating modes shown in Figure 2.4.2.1 take place in this IC.

#### RUN mode

RUN mode refers to the state in which the CPU is executing the program. A transition to this mode takes place when the system reset request from the system reset controller is canceled. RUN mode is classified into “IOSC RUN,” “OSC1 RUN,” “OSC3 RUN,” and “EXOSC RUN” by the SYSCLK clock source.

#### HALT mode

When the CPU executes the halt instruction, it suspends program execution and stops operating. This state is HALT mode. In this mode, the clock sources and peripheral circuits keep operating. This mode can be set while no software processing is required and it reduces power consumption as compared with RUN mode. HALT mode is classified into “IOSC HALT,” “OSC1 HALT,” “OSC3 HALT,” and “EXOSC HALT” by the SYSCLK clock source.

#### SLEEP mode

When the CPU executes the slp instruction, it suspends program execution and stops operating. This state is SLEEP mode. In this mode, the clock sources stop operating as well. However, the clock source in which the CLGOSC.IOSCSLPC/OSC1SLPC/OSC3SLPC/EXOSCSLPC bit is set to 0 keeps operating, so the peripheral circuits with the clock being supplied can also operate. By setting this mode when no software processing and peripheral circuit operations are required, power consumption can be less than HALT mode.

**Note:** The current consumption when a clock source is active in SLEEP mode by setting the CLGOSC.IOSCSLPC/OSC1SLPC/OSC3SLPC/EXOSCSLPC bit to 0 is equivalent to the value in HALT mode with the same clock source condition (refer to “Current Consumption, Current consumption in HALT mode  $I_{HALT1}$ ,  $I_{HALT2}$ , and  $I_{HALT3}$ ” in the “Electrical Characteristics” chapter).

#### DEBUG mode

When a debug interrupt occurs, the CPU enters DEBUG mode. DEBUG mode is canceled when the retd instruction is executed. For more information on DEBUG mode, refer to “Debugger” in the “CPU and Debugger” chapter.

Figure 2.4.2.1 Operating Mode-to-Mode State Transition Diagram

### Canceling HALT or SLEEP mode

The conditions listed below generate the HALT/SLEEP cancelation signal to cancel HALT or SLEEP mode and put the CPU into RUN mode. This transition is executed even if the CPU does not accept the interrupt request.

- Interrupt request from a peripheral circuit
- NMI from the watchdog timer
- Debug interrupt
- Reset request

## 2.5 Interrupts

PWG2 and CLG have a function to generate the interrupts shown in Table 2.5.1.

Table 2.5.1 PWG2 and CLG Interrupt Functions

Interrupt	Interrupt flag	Set condition	Clear condition
PWG2 mode transition completion	PWGINTF.MODCMPIF	When the transition from super economy mode to another mode has completed, or when the transition from normal mode to economy mode has completed in automatic mode (See Notes below.)	Writing 1
IOSC oscillation stabilization waiting completion	CLGINTF.IOSCSTAIF	When the IOSC oscillation stabilization waiting operation has completed after the oscillation starts	Writing 1
OSC1 oscillation stabilization waiting completion	CLGINTF.OSC1STAIF	When the OSC1 oscillation stabilization waiting operation has completed after the oscillation starts	Writing 1
OSC3 oscillation stabilization waiting completion	CLGINTF.OSC3STAIF	When the OSC3 oscillation stabilization waiting operation has completed after the oscillation starts	Writing 1
OSC1 oscillation stop	CLGINTF.OSC1STPIF	When OSC1CLK is stopped, or when the CLGOSC.OSC1EN or CLGOSC1.OSDEN bit setting is altered from 1 to 0.	Writing 1
IOSC oscillation auto-trimming completion	CLGINTF.IOSCTEDIF	When the IOSC oscillation auto-trimming operation has completed	Writing 1

CLG provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

- Notes:**
- The PWGINTF.MODCMPIF bit is set to 1 if a condition shown above is met only when the OSC1 oscillator circuit is operating regardless of RUN or SLEEP mode.
  - When a transition, from RUN mode in which the system runs with a high-speed clock to SLEEP mode in which the OSC1 oscillator circuit only operates (high-speed clocks are halted), has occurred in automatic mode, the PWGINTF.MODCMPIF bit is set to 1 after a lapse of 1 ms from entering SLEEP mode. If the PWGINTE.MODCMPIE bit = 1 at this point, an interrupt occurs and the CPU wakes up from SLEEP mode. When putting the CPU to SLEEP mode with the OSC1 oscillator circuit activated, set the PWGINTE.MODCMPIE bit to 0.

## 2.6 Control Registers

### PWG2 Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PWGCTL	15–8	–	0x00	–	R	–

	2–0	PWGMOD[2:0]	0x0	H0	R/WP	

**Bits 15–3 Reserved**

**Bits 2–0 PWGMOD[2:0]**

These bits control the PWG2 operating mode.

Table 2.6.1 PWG2 Operating Mode

PWGCTL.PWGMOD[2:0] bits	Operating mode
0x7–0x6	Reserved
0x5	Super economy mode
0x4	Reserved
0x3	Economy mode
0x2	Normal mode
0x1	Reserved
0x0	Automatic mode

**Note:** The PWGCTL.PWGMOD[2:0] bits are set to 0x0 when 0x7, 0x6, 0x4, or 0x1 is written.

## PWG2 Timing Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PWGTIM	15–8	–	0x00	–	R	–
	7–2	–	0x00	–	R	
	1–0	DCCCLK[1:0]	0x0	H0	R/WP	

**Bits 15–2 Reserved**

**Bits 1–0 DCCCLK[1:0]**

These bits set the charge pump operating clock (select an OSC1 clock division ratio).

PWGINTF	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	MODCMPIF	0	H0	R/W	

**Bits 15–1 Reserved**

**Bit 0 MODCMPIF**

This bit indicates the PWG2 mode transition completion interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

## PWG2 Interrupt Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PWGINTE	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	MODCMPIE	0	H0	R/W	

**Bits 15–1 Reserved**

**Bit 0 MODCMPIE**

These bits enable the PWG2 mode transition completion interrupt.

1 (R/W): Enable interrupt

0 (R/W): Disable interrupt

## CLG System Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
CLGSCLK	15	WUPMD	0	H0	R/WP	–
	14	–	0	–	R	
	13–12	WUPDIV[1:0]	0x0	H0	R/WP

	5–4	CLKDIV[1:0]	0x0	H0	R/WP	
	3–2	–	0x0	–	R	
	1–0	CLKSRC[1:0]	0x0	H0	R/WP	

**Bit 15 WUPMD**

This bit enables the SYSCLK switching function at wake-up.

- 1 (R/WP): Enable
- 0 (R/WP): Disable

When the CLGSCLK.WUPMD bit = 1, setting values of the CLGSCLK.WUPSRC[1:0] bits and the CLGSCLK.WUPDIV[1:0] bits are loaded to the CLGSCLK.CLKSRC[1:0] bits and the CLGSCLK.CLKDIV[1:0] bits, respectively, at wake-up from SLEEP mode to switch SYSCLK. When the CLGSCLK.WUPMD bit = 0, the CLGSCLK.CLKSRC[1:0] and CLGSCLK.CLKDIV[1:0] bits are not altered at wake-up.

**Note:** When the CLGSCLK.WUPMD bit = 1, the clock source enable bits (CLGOSC.EXOSCEN, CLGOSC.OSC1EN, CLGOSC.OSC3EN, CLGOSC.IOSCEN) except for the SYSCLK source selected by the CLGSCLK.CLKSRC[1:0] bits will be cleared to 0 to stop the clocks after a system wake-up. However, the enable bit of the clock source being operated during SLEEP mode by setting the CLGOSC.\*\*\*\*SLPC bit retains 1 after a wake-up.

**Bit 14 Reserved**

**Bits 13–12 WUPDIV[1:0]**

These bits select the SYSCLK division ratio for resetting the CLGSCLK.CLKDIV[1:0] bits at wake-up. This setting is ineffective when the CLGSCLK.WUPMD bit = 0.

**Bits 11–10 Reserved**

**Bits 9–8 WUPSRC[1:0]**

These bits select the SYSCLK clock source for resetting the CLGSCLK.CLKSRC[1:0] bits at wake-up. When a currently stopped clock source is selected, it will automatically start oscillating or clock input at wake-up. However, this setting is ineffective when the CLGSCLK.WUPMD bit = 0.

0x0	1/1	1/1	1/1	1/1

**Bits 7–6 Reserved**

**Bits 5–4 CLKDIV[1:0]**

These bits set the division ratio of the clock source to determine the SYSCLK frequency.

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the SYSCLK clock source.

When a currently stopped clock source is selected, it will automatically start oscillating or clock input.

### Bits 15–12 Reserved

**Bit 11** EXOSCSLPC

**Bit 10** OSC3SLPC

**Bit 9** OSC1SLPC

**Bit 8** IOSCSLPC

These bits control the clock source operations in SLEEP mode.

1 (R/W): Stop clock source in SLEEP mode

0 (R/W): Continue operation state before SLEEP

Each bit corresponds to the clock source as follows:

CLGOSC.EXOSCSLPC bit: EXOSC clock input

CLGOSC.OSC3SLPC bit: OSC3 oscillator circuit

CLGOSC.OSC1SLPC bit: OSC1 oscillator circuit

CLGOSC.IOSCSLPC bit: IOSC oscillator circuit

### Bits 7–4 Reserved

**Bit 3** EXOSCEN

**Bit 2** OSC3EN

**Bit 1** OSC1EN

**Bit 0** IOSCEN

These bits control the clock source operation.

1(R/W): Start oscillating or clock input

0(R/W): Stop oscillating or clock input

Each bit corresponds to the clock source as follows:

CLGOSC.EXOSCEN bit: EXOSC clock input

CLGOSC.OSC3EN bit: OSC3 oscillator circuit

CLGOSC.OSC1EN bit: OSC1 oscillator circuit

CLGOSC.IOSCEN bit: IOSC oscillator circuit

### Bits 15–5 Reserved

## 2 POWER SUPPLY, RESET, AND CLOCKS

### Bit 4 IOS CSTM

This bit controls the IOS CCLK auto-trimming function.

1 (WP): Start trimming

0 (WP): Stop trimming

1 (R): Trimming is executing.

0 (R): Trimming has finished. (Trimming operation inactivated.)

This bit is automatically cleared to 0 when trimming has finished.

**Notes:**

- Do not use IOS CCLK as the system clock or peripheral circuit clocks while the CLG IOS C. IOS CSTM bit = 1.

- The auto-trimming function does not work if the OSC1 oscillator circuit is stopped. Make sure the CLG INTF.OSC1 STAIF bit is set to 1 before starting the trimming operation.

### Bits 3–0 Reserved

1–0	OSC1WT[1:0]	0x2	H0	R/WP		

### Bit 15 Reserved

### Bit 14 OSDRB

This bit enables the OSC1 oscillator circuit restart function by the oscillation stop detector when OSC1 oscillation stop is detected.

1 (R/WP): Enable (Restart the OSC1 oscillator circuit when oscillation stop is detected.)

0 (R/WP): Disable

### Bit 13 OSDEN

This bit controls the oscillation stop detector in the OSC1 oscillator circuit.

1 (R/WP): OSC1 oscillation stop detector on

0 (R/WP): OSC1 oscillation stop detector off

**Note:** Do not write 1 to the CLG OSC1.OSDEN bit before stabilized OSC1CLK is supplied. Furthermore, the CLG OSC1.OSDEN bit should be set to 0 when the CLG OSC.OSC1EN bit is set to 0.

### Bit 12 OSC1BUP

This bit enables the oscillation startup control circuit in the OSC1 oscillator circuit.

1 (R/WP): Enable (Activate booster operation at startup.)

0 (R/WP): Disable

### Bit 11 Reserved

These bits indicate the OSC1 oscillation stop and IOSC oscillation auto-trimming completion interrupt cause occurrence statuses.

- 1 (R): Cause of interrupt occurred
- 0 (R): No cause of interrupt occurred
- 1 (W): Clear flag
- 0 (W): Ineffective

Each bit corresponds to the interrupt as follows:

CLGINTF.OSC1STPIF bit: OSC1 oscillation stop interrupt

CLGINTF.IOSCTEDIF bit: IOSC oscillation auto-trimming completion interrupt

#### Bit 3 Reserved

#### Bit 2 OSC3STAIF

#### Bit 1 OSC1STAIF

#### Bit 0 IOSCSTAIF

These bits indicate the oscillation stabilization waiting completion interrupt cause occurrence status in each clock source.

- 1 (R): Cause of interrupt occurred
- 0 (R): No cause of interrupt occurred
- 1 (W): Clear flag
- 0 (W): Ineffective

Each bit corresponds to the clock source as follows:

CLGINTF.OSC3STAIF bit: OSC3 oscillator circuit

CLGINTF.OSC1STAIF bit: OSC1 oscillator circuit

CLGINTF.IOSCSTAIF bit: IOSC oscillator circuit

**Note:** The CLGINTF.IOSCSTAIF bit is 0 after system reset is canceled, but IOSCCLK has already been stabilized.

**Note:** When the CLGFOUT.FOUTSRC[1:0] bits are set to 0x3, the FOUT output will be stopped in SLEEP/HALT mode as SYSCLK is stopped.

### Bit 1 Reserved

**Bit 0 FOUTEN**

This bit controls the FOUT clock external output.

1 (R/W): Enable external output

0 (R/W): Disable external output

**Note:** Since the FOUT signal generated is out of sync with writings to the CLGFOUT.FOUTEN bit, a glitch may occur when the FOUT output is enabled or disabled.

# 3 CPU and Debugger

## 3.1 Overview

This IC incorporates the Seiko Epson original 16-bit CPU core (S1C17) with a debugger. The main features of the CPU core are listed below.

- Seiko Epson original 16-bit RISC processor
  - 24-bit general-purpose registers: 8
  - 24-bit special registers: 2
  - 8-bit special register: 1
  - Up to 16M bytes of memory space (24-bit address)
  - Harvard architecture using separated instruction bus and data bus
- Compact and fast instruction set optimized for development in C language
  - Code length: 16-bit fixed length
  - Number of instructions: 111 basic instructions (184 including variations)
  - Execution cycle: Main instructions are executed in one cycle.
  - Extended immediate instructions: Immediate data can be extended up to 24 bits.
- Supports reset, NMI, address misaligned, debug, and external interrupts.
  - Reads a vector from the vector table and branches to the interrupt handler routine directly.
  - Can generate software interrupts with a vector number specified (all vector numbers specifiable).
- HALT mode (halt instruction) and SLEEP mode (slp instruction) are provided as the standby function.
- Incorporates a debugger with three-wire communication interface to assist in software development.

Figure 3.1.1 S1C17 Configuration

## 3.2 CPU Core

---

### 3.2.1 CPU Registers

The CPU includes eight general-purpose registers and three special registers (Table 3.2.1.1).

Table 3.2.1.1 Initialization of CPU Registers

CPU register name			Initial	Reset
General-purpose registers		R0 to R7	0x000000	H0
Special registers	Program counter	PC	The reset vector is automatically loaded.	H0
	Stack pointer	SP	0x000000	H0
	Processor status register	PSR	0x00	H0

For details on the CPU registers, refer to the “S1C17 Family S1C17 Core Manual.” For more information on the reset vector, refer to the “Interrupt Controller” chapter.

### 3.2.2 Instruction Set

The CPU instruction codes are all fixed to 16 bits in length which, combined with pipelined processing, allows the most important instructions to be executed in one cycle. For details on the instructions, refer to the “S1C17 Family S1C17 Core Manual.”

### 3.2.3 Reading PSR

The PSR contents can be read through the MSCPSR register. Note, however, that data cannot be written to PSR through the MSCPSR register.

### 3.2.4 I/O Area Reserved for the S1C17 Core

The address range from 0xffffc00 to 0xfffffff is the I/O area reserved for the S1C17 core. Do not access this area except when it is required.

## 3.3 Debugger

---

### 3.3.1 Debugging Functions

The debugger provides the following functions:

- **Instruction break:** A debug interrupt is generated immediately before the set instruction address is executed. An instruction break can be set at up to four addresses.
- **Single step:** A debug interrupt is generated after each instruction has been executed.
- **Forcible break:** A debug interrupt is generated using an external input signal.
- **Software break:** A debug interrupt is generated when the brk instruction is executed.

When a debug interrupt occurs, the CPU enters DEBUG mode. The peripheral circuit operations in DEBUG mode depend on the setting of the DBRUN bit provided in the clock control register of each peripheral circuit. For more information on the DBRUN bit, refer to “Clock Supply in DEBUG Mode” in each peripheral circuit chapter. DEBUG mode continues until a cancel command is sent from the personal computer or the CPU executes the retid instruction. Neither hardware interrupts nor NMI are accepted during DEBUG mode.

### 3.3.2 Resource Requirements and Debugging Tools

#### Debugging work area

Debugging requires a 64-byte debugging work area. For more information on the work area location, refer to the “Memory and Bus” chapter. The start address of this debugging work area can be read from the DBRAM register.

## Debugging tools

To perform debugging, connect ICDmini (S5U1C17001H) to the input/output pin for the debugger embedded in this IC and control it from the personal computer. This requires the tools shown below.

- S1C17 Family In-Circuit Debugger ICDmini (S5U1C17001H)
- S1C17 Family C Compiler Package (e.g., S5U1C17001C)

### 3.3.3 List of Debugger Input/Output Pins

Table 3.3.3.1 lists the debug pins.

Table 3.3.3.1 List of Debug Pins

Pin name	I/O	Initial state	Function
DCLK	O	0	On-chip debugger clock output pin Outputs a clock to the ICDmini (S5U1C17001H).
DSIO	I/O	1	On-chip debugger data input/output pin Used to input/output debugging data and input the break signal.
DST2	O	0	On-chip debugger status output pin Outputs the processor status during debugging.

The debugger input/output pins are shared with general-purpose I/O ports and are initially set as the debug pins. If the debugging function is not used, these pins can be switched to general-purpose I/O port pins. For details, refer to the “I/O Ports” chapter.

### 3.3.4 External Connection

Figure 3.3.4.1 shows a connection example between this IC and ICDmini when performing debugging.

Figure 3.3.4.1 External Connection

For the recommended pull-up resistor value, refer to “Recommended Operating Conditions, DSIO pull-up resistor  $R_{DBG}$ ” in the “Electrical Characteristics” chapter.  $R_{DBG}$  is not required when using the DSIO pin as a general-purpose I/O port pin.

### 3.3.5 Flash Security Function

This IC provides a security function to protect the internal Flash memory from unauthorized reading and tampering by using the debugger through ICDmini. Figure 3.3.5.1 shows a Flash security function setting flow.

Figure 3.3.5.1 Shipment of IC with ROM Data Programmed and Flash Security Function Setting Flow

The following shows the status of the IC with protected Flash:

- The Flash memory data is undefined if it is read from the debugger.
- An error occurs if an attempt is made to program the Flash memory through ICDmini.

### 3 CPU AND DEBUGGER

However, the Flash security function can be disabled by entering the unprotecting password predefined to GNU17 IDE (the security function will take effect again after a reset). For setting the password, refer to the “(S1C17 Family C Compiler Package) S5U1C17001C Manual.”

**Note:** Disable the Flash security function before debugging an IC with protected Flash via ICDmini. The debugging functions may not run normally if the Flash security function is enabled.

## 3.4 Control Register

### MISC PSR Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
MSCPSR	15–8	–	0x00	–	R	–
	7–5	PSRIL[2:0]	0x0	H0	R	
	4	PSRIE	0	H0	R	
	3	PSRC	0	H0	R	
	2	PSRV	0	H0	R	
	1	PSRZ	0	H0	R	
	0	PSRN	0	H0	R	

**Bits 15–8 Reserved**

**Bits 7–5 PSRIL[2:0]**

The value (0 to 7) of the PSR IL[2:0] (interrupt level) bits can be read out with these bits.

**Bit 4 PSRIE**

The value (0 or 1) of the PSR IE (interrupt enable) bit can be read out with this bit.

**Bit 3 PSRC**

The value (0 or 1) of the PSR C (carry) flag can be read out with this bit.

**Bit 2 PSRV**

The value (0 or 1) of the PSR V (overflow) flag can be read out with this bit.

**Bit 1 PSRZ**

The value (0 or 1) of the PSR Z (zero) flag can be read out with this bit.

**Bit 0 PSRN**

The value (0 or 1) of the PSR N (negative) flag can be read out with this bit.

### Debug RAM Base Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
DBRAM	31–24	–	0x00	–	R	–
	23–0	DBRAM[23:0]	*1	H0	R	

\*1 Debugging work area start address

**Bits 31–24 Reserved**

**Bits 23–0 DBRAM[23:0]**

The start address of the debugging work area (64 bytes) can be read out with these bits.

# 4 Memory and Bus

## 4.1 Overview

This IC supports up to 16M bytes of accessible memory space for both instructions and data.

The features are listed below.

- Embedded Flash memory that supports on-board programming
- All memory and control registers are accessible in 16-bit width and one cycle.
- Write-protect function to protect system control registers

Figure 4.1.1 shows the memory map.

Figure 4.1.1 Memory Map

## 4.2 Bus Access Cycle

The CPU uses the system clock for bus access operations. First, “Bus access cycle,” “Device size,” and “Access size” are defined as follows:

- Bus access cycle: One system clock period = 1 cycle
- Device size: Bit width of the memory and peripheral circuits that can be accessed in one cycle
- Access size: Access size designated by the CPU instructions (e.g., `ld %rd, [%rb]` → 16-bit data transfer)

Table 4.2.1 lists numbers of bus access cycles by different device size and access size. The peripheral circuits can be accessed with an 8-bit, 16-bit, or 32-bit instruction.

Table 4.2.1 Number of Bus Access Cycles

Device size	Access size	Number of bus access cycles
8 bits	8 bits	1
	16 bits	2
	32 bits	4
16 bits	8 bits	1
	16 bits	1
	32 bits	2
32 bits	8 bits	1
	16 bits	1
	32 bits	1

**Note:** When data is transferred to a memory in 32-bit access, the eight high-order bits are written to the memory as 0x00 since the bit width of the S1C17 core general-purpose registers is 24 bits. Conversely when sending from a memory to a register, the eight high-order bits are ignored. The CPU performs 32-bit access for stack operations in an interrupt handling. In this case, the CPU read/write 32-bit data that consists of the PSR value as the eight high-order bits and the return address as the 24 low-order bits. For more information, refer to the “S1C17 Family S1C17 Core Manual.”

The CPU adopts Harvard architecture that allows simultaneous processing of an instruction fetch and a data access. However, they are not performed simultaneously under one of the conditions listed below. This prolongs the instruction fetch cycle for the number of data area bus cycles.

- When the CPU executes an instruction stored in the Flash area and accesses data in the Flash area
- When the CPU executes an instruction stored in the internal RAM area and accesses data in the internal RAM area

## 4.3 Flash Memory

The Flash memory is used to store application programs and data. Address 0x8000 in the Flash area is defined as the vector table base address by default, therefore a vector table must be located beginning from this address. For more information on the vector table, refer to “Vector Table” in the “Interrupt Controller” chapter.

### 4.3.1 Flash Memory Pin

Table 4.3.1.1 shows the Flash memory pin.

Table 4.3.1.1 Flash Memory Pin

Pin name	I/O	Initial status	Function
V <sub>PP</sub>	P	–	Flash programming power supply

For the V<sub>PP</sub> voltage, refer to “Recommended Operating Conditions, Flash programming voltage V<sub>PP</sub>” in the “Electrical Characteristics” chapter.

**Note:** Always leave the V<sub>PP</sub> pin open except when programming the Flash memory.

### 4.3.2 Flash Bus Access Cycle Setting

There is a limit of frequency to access the Flash memory with no wait cycle, therefore, the number of bus access cycles for reading must be changed according to the system clock frequency. The number of bus access cycles for reading can be configured using the FLASHWAIT.RDWAIT[1:0] bits. Select a setting for higher frequency than the system clock.

### 4.3.3 Flash Programming

The Flash memory supports on-board programming, so it can be programmed with the ROM data by using the debugger through an ICDmini. Figure 4.3.3.1 shows a connection diagram for on-board programming.

Figure 4.3.3.1 External Connection

The VPP pin must be left open except when programming the Flash memory. However, it is not necessary to disconnect the wire when using ICDmini to supply the VPP power, as ICDmini controls the power supply so that it will be supplied during Flash programming only. CVPP should be connected if the VPP voltage is not stable due to the effect of the distance between the VPP and Flash Vcc OUT or other causes.

For detailed information on ROM data programming method, refer to the “(S1C17 Family C Compiler Package) S5U1C17001C Manual.” The IC can also be shipped after being programmed in the factory with the ROM data developed. Should you desire to ship the IC with ROM data programmed from the factory, please contact our customer support.

**Note:** The Flash programming requires a 1.8 V or higher VDD voltage.

## 4.4 RAM

The RAM can be used to execute the instruction codes copied from another memory as well as storing variables or other data. This allows higher speed processing and lower power consumption than Flash memory.

**Note:** The 64 bytes at the end of the RAM is reserved as the debug RAM area. When using the debug functions under application development, do not access this area from the application program. This area can be used for applications of mass-produced devices that do not need debugging.

The RAM size used by the application can be configured to equal or less than the implemented size using the MSCIRAMSZ.IRAMSZ[2:0] bits. For example, this function can be used to prevent creating programs that seek to access areas outside the RAM area of the target model when developing an application for a model in which the RAM size is smaller than this IC. After the limitation is applied, accessing an address outside the RAM area results in the same operation (undefined value is read out) as when a reserved area is accessed.

## 4.5 Peripheral Circuit Control Registers

The control registers for the peripheral circuits are located in the 8K-byte area beginning with address 0x4000. Table 4.5.1 shows the control register map. For details of each control register, refer to “List of Peripheral Circuit Registers” in the appendix or “Control Registers” in each peripheral circuit chapter.

### 4.5.1 System-Protect Function

The system-protect function protects control registers and bits from writings. They cannot be rewritten unless write protection is removed by writing 0x0096 to the MSCPROT.PROT[15:0] bits. This function is provided to prevent deadlock that may occur when a system-related register is altered by a runaway CPU. See “Control Registers” in each peripheral circuit to identify the registers and bits with write protection.

**Note:** Once write protection is removed using the MSCPROT.PROT[15:0] bits, write enabled status is maintained until write protection is applied again. After the registers/bits required have been altered, apply write protection.

## 4.6 Control Registers

### MISC System Protect Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
MSCPROT	15–0	PROT[15:0]	0x0000	H0	R/W	–

#### Bits 15–0 PROT[15:0]

These bits protect the control registers related to the system against writings.

0x0096 (R/W): Disable system protection

Other than 0x0096 (R/W): Enable system protection

While the system protection is enabled, any data will not be written to the affected control bits (bits with “WP” or “R/WP” appearing in the R/W column).

#### Bits 15–8 Reserved

#### Bit 7 XBUSY

This bit indicates whether the Flash memory can be accessed or not.

1 (R): Flash memory ready to access

0 (R): Flash access prohibited

The Flash memory can always be accessed during normal operation.

**Bits 6–2** Reserved

**Bits 1–0** RDWAIT[1:0]

These bits set the number of bus access cycles for reading from the Flash memory.

0x0	1	2.1 MHz (max.)

**Note:** Be sure to set the FLASHWAIT.RDWAIT[1:0] bits before the system clock is configured.

# 5 Interrupt Controller (ITC)

## 5.1 Overview

The features of the ITC are listed below.

- Honors interrupt requests from the peripheral circuits and outputs the interrupt request, interrupt level and vector number signals to the CPU.
- The interrupt level of each interrupt source is selectable from among eight levels.
- Priorities of the simultaneously generated interrupts are established from the interrupt level.
- Handles the simultaneously generated interrupts with the same interrupt level as smaller vector number has higher priority.

Figure 5.1.1 shows the configuration of the ITC.

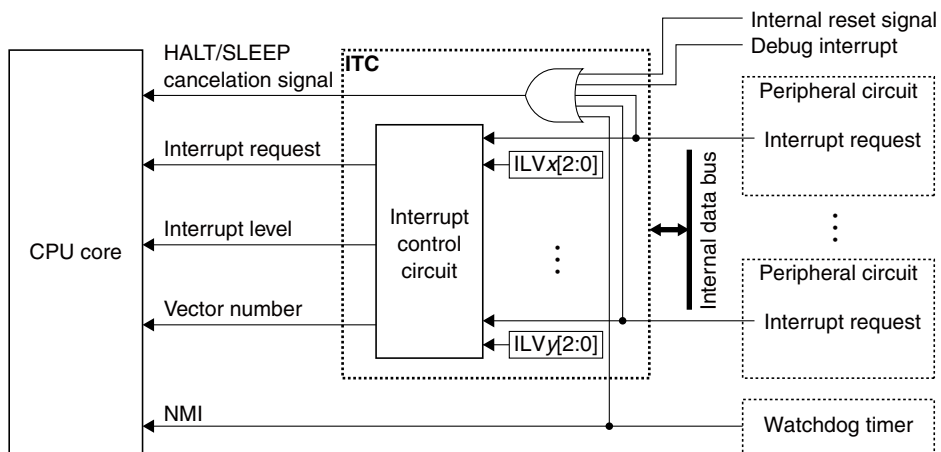

Figure 5.1.1 ITC Configuration

## 5.2 Vector Table

The vector table contains the vectors to the interrupt handler routines (handler routine start address) that will be read by the CPU to execute the handler when an interrupt occurs.

Table 5.2.1 shows the vector table.

## 5.2.1 Vector Table Base Address (TTBR)

The MSCTTBRL and MSCTTBRH registers are provided to set the base (start) address of the vector table in which interrupt vectors are programmed. “TTBR” described in Table 5.2.1 means the value set to these registers. After an initial reset, the MSCTTBRL and MSCTTBRH registers are set to address 0x8000. Therefore, even when the vector table location is changed, it is necessary that at least the reset vector be written to the above address. Bits 7 to 0 in the MSCTTBRL register are fixed at 0, so the vector table always begins from a 256-byte boundary address.

## 5.3 Initialization

The following shows an example of the initial setting procedure related to interrupts:

1. Execute the di instruction to set the CPU into interrupt disabled state.
2. If the vector table start address is different from the default address, set it to the MSCTTBRL and MSCTTBRH registers after removing system protection by writing 0x0096 to the MSCPROT.PROT[15:0] bits. Then, write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits to set system protection.
3. Set the interrupt enable bit of the peripheral circuit to 0 (interrupt disabled).
4. Set the interrupt level for the peripheral circuit using the ITCLV<sub>x</sub>.ILV<sub>x</sub>[2:0] bits in the ITC.
5. Configure the peripheral circuit and start its operation.
6. Clear the interrupt factor flag of the peripheral circuit.
7. Set the interrupt enable bit of the peripheral circuit to 1 (interrupt enabled).
8. Execute the ei instruction to set the CPU into interrupt enabled state.

## 5.4 Maskable Interrupt Control and Operations

### 5.4.1 Peripheral Circuit Interrupt Control

The peripheral circuit that generates interrupts includes an interrupt enable bit and an interrupt flag for each interrupt cause.

**Interrupt flag:** The flag is set to 1 when the interrupt cause occurs. The clear condition depends on the peripheral circuit.

**Interrupt enable bit:** By setting this bit to 1 (interrupt enabled), an interrupt request will be sent to the ITC when the interrupt flag is set to 1. When this bit is set to 0 (interrupt disabled), no interrupt request will be sent to the ITC even if the interrupt flag is set to 1. An interrupt request is also sent to the ITC if the status is changed to interrupt enabled when the interrupt flag is 1.

For specific information on causes of interrupts, interrupt flags, and interrupt enable bits, refer to the respective peripheral circuit descriptions.

**Note:** To prevent occurrence of unnecessary interrupts, the corresponding interrupt flag should be cleared before setting the interrupt enable bit to 1 (interrupt enabled) and before terminating the interrupt handler routine.

### 5.4.2 ITC Interrupt Request Processing

On receiving an interrupt signal from a peripheral circuit, the ITC sends an interrupt request, the interrupt level, and the vector number to the CPU. Vector numbers are determined by the ITC internal hardware for each interrupt cause, as shown in Table 5.2.1. The interrupt level is a value to configure the priority, and it can be set to between 0 (low) and 7 (high) using the  $ITCLVx.ILVx[2:0]$  bits provided for each interrupt source. The default ITC settings are level 0 for all maskable interrupts. Interrupt requests are not accepted by the CPU if the level is 0.

The ITC outputs the interrupt request with the highest priority to the CPU in accordance with the following conditions if interrupt requests are input to the ITC simultaneously from two or more peripheral circuits.

- The interrupt with the highest interrupt level takes precedence.
- If multiple interrupt requests are input with the same interrupt level, the interrupt with the lowest vector number takes precedence.

The other interrupts occurring at the same time are held until all interrupts with higher priority levels have been accepted by the CPU.

If an interrupt cause with higher priority occurs while the ITC is outputting an interrupt request signal to the CPU (before being accepted by the CPU), the ITC alters the vector number and interrupt level signals to the setting information on the more recent interrupt. The previously occurring interrupt is held. The held interrupt is canceled and no interrupt is generated if the interrupt flag in the peripheral circuit is cleared via software.

**Note:** Before changing the interrupt level, make sure that no interrupt of which the level is changed can be generated (the interrupt enable bit of the peripheral circuit is set to 0 or the peripheral circuit is deactivated).

### 5.4.3 Conditions to Accept Interrupt Requests by the CPU

The CPU accepts an interrupt request sent from the ITC when all of the following conditions are met:

- The IE (Interrupt Enable) bit of the PSR has been set to 1.
- The interrupt request that has occurred has a higher interrupt level than the value set in the  $IL[2:0]$  (Interrupt Level) bits of the PSR.
- No other interrupt request having higher priority, such as NMI, has occurred.

## 5.5 NMI

---

The watchdog timer embedded in this IC can generate a non-maskable interrupt (NMI). This interrupt takes precedence over other interrupts and is unconditionally accepted by the CPU.

For detailed information on generating NMI, refer to the “Watchdog Timer” chapter.

## 5.6 Software Interrupts

---

The CPU provides the “`int imm5`” and “`intl imm5, imm3`” instructions allowing the software to generate any interrupts. The operand *imm5* specifies a vector number (0–31) in the vector table. In addition to this, the *intl* instruction has the operand *imm3* to specify the interrupt level (0–7) to be set to the  $IL[2:0]$  bits in the PSR. The software interrupt cannot be disabled (non-maskable interrupt). The processor performs the same interrupt processing operation as that of the hardware interrupt.

## 5.7 Interrupt Processing by the CPU

The CPU samples interrupt requests for each cycle. On accepting an interrupt request, the CPU switches to interrupt processing immediately after execution of the current instruction has been completed.

Interrupt processing involves the following steps:

1. The PSR and current program counter (PC) values are saved to the stack.
2. The PSR IE bit is cleared to 0 (disabling subsequent maskable interrupts).
3. The PSR IL[2:0] bits are set to the received interrupt level. (The NMI does not affect the IL bits.)
4. The vector for the interrupt occurred is loaded to the PC to execute the interrupt handler routine.

When an interrupt is accepted, Step 2 prevents subsequent maskable interrupts. Setting the IE bit to 1 in the interrupt handler routine allows handling of multiple interrupts. In this case, since the IL[2:0] bits are changed by Step 3, only an interrupt with a higher level than that of the currently processed interrupt will be accepted.

Ending interrupt handler routines using the `reti` instruction returns the PSR to the state before the interrupt occurred. The program resumes processing following the instruction being executed at the time the interrupt occurred.

**Note:** When HALT or SLEEP mode is canceled, the CPU jumps to the interrupt handler routine after executing one instruction. To execute the interrupt handler routine immediately after HALT or SLEEP mode is canceled, place the `nop` instruction at just behind the `halt/slp` instruction.

# 6 I/O Ports (PPORT)

## 6.1 Overview

PPORT controls the I/O ports. The main features are outlined below.

- Allows port-by-port function configurations.
  - Each port can be configured with or without a pull-up or pull-down resistor.
  - Each port can be configured with or without a chattering filter.
  - Allows selection of the function (general-purpose I/O port (GPIO) function, up to four peripheral I/O functions) to be assigned to each port.
- Ports, except for those shared with debug pins, are initially placed into Hi-Z state. (No current passes through the pin during this Hi-Z state.)

**Note:** 'x', which is used in the port names Pxy, register names, and bit names, refers to a port group (x = 0, 1, 2, ..., d) and 'y' refers to a port number (y = 0, 1, 2, ..., 7).

Figure 6.1.1 shows the configuration of PPORT.

## 6.2 I/O Cell Structure and Functions

Figure 6.2.1 shows the I/O cell Configuration.

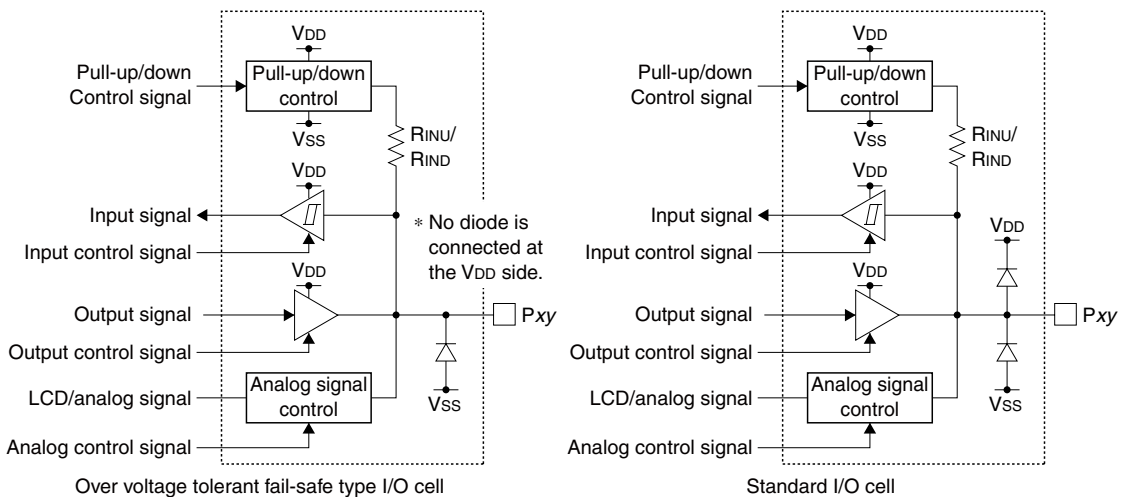

Figure 6.2.1 I/O Cell Configuration

Refer to “Pin Descriptions” in the “Overview” chapter for the cell type, either the over voltage tolerant fail-safe type I/O cell or the standard I/O cell, included in each port.

### 6.2.1 Schmitt Input

The input functions are all configured with the Schmitt interface level. When a port is set to input disable status (PxIOEN.PxIENy bit = 0), unnecessary current is not consumed if the Pxy pin is placed into floating status.

### 6.2.2 Over Voltage Tolerant Fail-Safe Type I/O Cell

The over voltage tolerant fail-safe type I/O cell allows interfacing without passing unnecessary current even if a voltage exceeding V<sub>DD</sub> is applied to the port. Also unnecessary current is not consumed when the port is externally biased without supplying V<sub>DD</sub>. However, be sure to avoid applying a voltage exceeding the recommended maximum operating power supply voltage to the port.

### 6.2.3 Pull-Up/Pull-Down

The GPIO port has a pull-up/pull-down function. Either pull-up or pull-down may be selected for each port individually. This function may also be disabled for the port that does not require pulling up/down.

When the port level is switched from low to high through the pull-up resistor included in the I/O cell or from high to low through the pull-down resistor, a delay will occur in the waveform rising/falling edge depending on the time constant by the pull-up/pull-down resistance and the pin load capacitance. The rising/falling time is commonly determined by the following equation:

$$\begin{aligned} t_{PR} &= -R_{INU} \times (C_{IN} + C_{BOARD}) \times \ln(1 - V_{T+}/V_{DD}) \\ t_{PF} &= -R_{IND} \times (C_{IN} + C_{BOARD}) \times \ln(1 - V_{T-}/V_{DD}) \end{aligned} \quad (\text{Eq. 6.1})$$

Where

- t<sub>PR</sub>: Rising time (port level = low → high) [second]
- t<sub>PF</sub>: Falling time (port level = high → low) [second]
- V<sub>T+</sub>: High level Schmitt input threshold voltage [V]
- V<sub>T-</sub>: Low level Schmitt input threshold voltage [V]
- R<sub>INU</sub>/R<sub>IND</sub>: Pull-up/pull-down resistance [Ω]
- C<sub>IN</sub>: Pin capacitance [F]
- C<sub>BOARD</sub>: Parasitic capacitance on the board [F]

## 6.2.4 CMOS Output and High Impedance State

The I/O cells except for analog output can output signals in the V<sub>DD</sub> and V<sub>SS</sub> levels. Also the GPIO ports may be put into high-impedance (Hi-Z) state.

## 6.3 Clock Settings

---

### 6.3.1 PPORT Operating Clock

When using the chattering filter for entering external signals to PPORT, the PPORT operating clock CLK\_PPORT must be supplied to PPORT from the clock generator.

The CLK\_PPORT supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
3. Set the following PCLK register bits:
 

- PCLK.CLKSRC[1:0] bits	(Clock source selection)
- PCLK.CLKDIV[3:0] bits	(Clock division ratio selection = Clock frequency setting)
4. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

Settings in Step 3 determine the input sampling time of the chattering filter.

### 6.3.2 Clock Supply in SLEEP Mode

When using the chattering filter function during SLEEP mode, the PPORT operating clock CLK\_PPORT must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_PPORT clock source.

If the CLGOSC.xxxxSLPC bit for the CLK\_PPORT clock source is 1, the CLK\_PPORT clock source is deactivated during SLEEP mode and it disables the chattering filter function regardless of the PxCHATEN.PxCHATENy bit setting (chattering filter enabled/disabled).

### 6.3.3 Clock Supply in DEBUG Mode

The CLK\_PPORT supply during DEBUG mode should be controlled using the PCLK.DBRUN bit.

The CLK\_PPORT supply to PPORT is suspended when the CPU enters DEBUG mode if the PCLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_PPORT supply resumes. The PPORT chattering filter stops operating when the CLK\_PPORT supply is suspended. If the chattering filter is enabled in PPORT, the input port function is also deactivated. However, the control registers can be altered. If the PCLK.DBRUN bit = 1, the CLK\_PPORT supply is not suspended and the chattering filter will keep operating in DEBUG mode.

## 6.4 Operations

---

### 6.4.1 Initialization

After a reset, the ports except for the debugging function are configured as shown below.

- Port input: Disabled
- Port output: Disabled
- Pull-up: Off
- Pull-down: Off
- Port pins: High impedance state
- Port function: Configured to GPIO

This status continues until the ports are configured via software. The debugging function ports are configured for debug signal input/output.

### Initial settings when using a port for a peripheral I/O function

When using the P<sub>xy</sub> port for a peripheral I/O function, perform the following software initial settings:

1. Set the following P<sub>x</sub>IOEN register bits:
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>IEN<sub>y</sub> bit to 0. (Disable input)
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>OEN<sub>y</sub> bit to 0. (Disable output)
2. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit to 0. (Disable peripheral I/O function)
3. Initialize the peripheral circuit that uses the pin.
4. Set the P<sub>x</sub>FNCSEL.P<sub>x</sub>MUX[1:0] bits. (Select peripheral I/O function)
5. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit to 1. (Enable peripheral I/O function)

For the list of the peripheral I/O functions that can be assigned to each port of this IC, refer to “Control Register and Port Function Configuration of this IC.” For the specific information on the peripheral I/O functions, refer to the respective peripheral circuit chapter.

### Initial settings when using a port as a general-purpose output port (only for the ports with GPIO function)

When using the P<sub>xy</sub> port pin as a general-purpose output pin, perform the following software initial settings:

1. Set the P<sub>x</sub>IOEN.P<sub>x</sub>OEN<sub>y</sub> bit to 1. (Enable output)
2. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit to 0. (Enable GPIO function)

### Initial settings when using a port as a general-purpose input port (only for the ports with GPIO function)

When using the P<sub>xy</sub> port pin as a general-purpose input pin, perform the following software initial settings:

1. Write 0 to the P<sub>x</sub>INTCTL.P<sub>x</sub>IE<sub>y</sub> bit. \* (Disable interrupt)
2. When using the chattering filter, configure the PPORT operating clock (see “PPORT Operating Clock”) and set the P<sub>x</sub>CHATEN.P<sub>x</sub>CHATEN<sub>y</sub> bit to 1. \*

When the chattering filter is not used, set the P<sub>x</sub>CHATEN.P<sub>x</sub>CHATEN<sub>y</sub> bit to 0 (supply of the PPORT operating clock is not required).

3. Configure the following P<sub>x</sub>RCTL register bits when pulling up/down the port using the internal pull-up or down resistor:
  - P<sub>x</sub>RCTL.P<sub>x</sub>PDP<sub>U</sub><sub>y</sub> bit (Select pull-up or pull-down resistor)
  - Set the P<sub>x</sub>RCTL.P<sub>x</sub>REN<sub>y</sub> bit to 1. (Enable pull-up/down)

Set the P<sub>x</sub>RCTL.P<sub>x</sub>REN<sub>y</sub> bit to 0 if the internal pull-up/down resistors are not used.

4. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit to 0. (Enable GPIO function)
5. Configure the following bits when using the port input interrupt: \*
  - Write 1 to the P<sub>x</sub>INTF.P<sub>x</sub>IF<sub>y</sub> bit. (Clear interrupt flag)
  - P<sub>x</sub>INTCTL.P<sub>x</sub>EDGE<sub>y</sub> bit (Select interrupt edge (input rising edge/falling edge))
  - Set the P<sub>x</sub>INTCTL.P<sub>x</sub>IE<sub>y</sub> bit to 1. (Enable interrupt)
6. Set the following P<sub>x</sub>IOEN register bits:
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>OEN<sub>y</sub> bit to 0. (Disable output)
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>IEN<sub>y</sub> bit to 1. (Enable input)

\* Steps 1 and 5 are required for the ports with an interrupt function. Step 2 is required for the ports with a chattering filter function.

Table 6.4.1.1 lists the port status according to the combination of data input/output control and pull-up/down control.

Table 6.4.1.1 GPIO Port Control List

PxIOEN. PxIENy bit	PxIOEN. PxOENy bit	PxRCTL. PxRENy bit	PxRCTL. PxPDPy bit	Input	Output	Pull-up/pull-down condition
0	0	0	×	Disabled		Off (Hi-Z) *1
0	0	1	0	Disabled		Pulled down
0	0	1	1	Disabled		Pulled up
1	0	0	×	Enabled	Disabled	Off (Hi-Z) *2
1	0	1	0	Enabled	Disabled	Pulled down
1	0	1	1	Enabled	Disabled	Pulled up
0	1	0	×	Disabled	Enabled	Off
0	1	1	0	Disabled	Enabled	Off
0	1	1	1	Disabled	Enabled	Off
1	1	1	0	Enabled	Enabled	Off
1	1	1	1	Enabled	Enabled	Off

\*1: Initial status. Current does not flow if the pin is placed into floating status.

\*2: Use of the pull-up or pull-down function is recommended, as undesired current will flow if the port input is set to floating status.

**Note:** If the PxMODSEL.PxSELy bit for the port without a GPIO function is set to 0, the port goes into initial status (refer to “Initial Settings”). The GPIO control bits are configured to a read-only bit always read out as 0.

## 6.4.2 Port Input/Output Control

### Peripheral I/O function control

The port for which a peripheral I/O function is selected is controlled by the peripheral circuit. For more information, refer to the respective peripheral circuit chapter.

### Setting output data to a GPIO port

Write data (1 = high output, 0 = low output) to be output from the Pxy pin to the PxDAT.PxOUTy bit.

### Reading input data from a GPIO port

The data (1 = high input, 0 = low input) input from the Pxy pin can be read out from the PxDAT.PxINy bit.

**Note:** The PxDAT.PxINy bit retains the input port status at 1 clock before being read from the CPU.

### Chattering filter function

Some ports have a chattering filter function and it can be controlled in each port. This function is enabled by setting the PxCHATEN.PxCHATENy bit to 1. The input sampling time to remove chattering is determined by the CLK\_PPORF frequency configured using the PCLK register in common to all ports. The chattering filter removes pulses with a shorter width than the input sampling time.

$$\text{Input sampling time} = \frac{2 \text{ to } 3}{\text{CLK\_PPORF frequency [Hz]}} \text{ [second]} \quad (\text{Eq.6.2})$$

Make sure the Pxy port interrupt is disabled before altering the PCLK register and PxCHATEN.PxCHATENy bit settings. A Pxy port interrupt may erroneously occur if these settings are altered in an interrupt enabled status. Furthermore, enable the interrupt after a lapse of four or more CLK\_PPORF cycles from enabling the chattering filter function.

If the clock generator is configured so that it will supply CLK\_PPORF to PPORT in SLEEP mode, the chattering filter of the port will function even in SLEEP mode. If CLK\_PPORF is configured to stop in SLEEP mode, PPORT inactivates the chattering filter during SLEEP mode to input pin status transitions directly to itself.

### Key-entry reset function

This function issues a reset request when low-level pulses are input to all the specified ports simultaneously. Make the following settings when using this function:

1. Configure the ports to be used for key-entry reset as general-purpose input ports (refer to “Initial settings when using a port as a general-purpose input port (only for the ports with GPIO function)”).
2. Configure the input pin combination for key-entry reset using the PCLK.KRSTCFG[1:0] bits.

**Note:** When enabling the key-entry reset function, be sure to configure the port pins to be used for it as general-purpose input pins before setting the PCLK.KRSTCFG[1:0] bits.

PPORT issues a reset request immediately after all the input pins specified by the PCLK.KRSTCFG[1:0] are set to a low level if the chattering filter function is disabled (initial status). To issue a reset request only when low-level signals longer than the time configured are input, enable the chattering filter function for all the ports used for key-entry reset.

The pins configured for key-entry reset can also be used as general-purpose input pins.

## 6.5 Interrupts

When the GPIO function is selected for the port with an interrupt function, the port input interrupt function can be used.

Table 6.5.1 Port Input Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Port input interrupt	PxINTF.PxIFy	Rising or falling edge of the input signal	Writing 1
	PINTFGRP.PxINT	Setting an interrupt flag in the port group	Clearing PxINTF.PxIFy

### Interrupt edge selection

Port input interrupts will occur at the falling edge of the input signal when setting the PxINTCTL.PxEDGEy bit to 1, or the rising edge when setting to 0.

### Interrupt enable

PPORT provides interrupt enable bits (PxINTCTL.PxIEy bit) corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

### Interrupt check in port group unit

When interrupts are enabled in two or more port groups, check the PINTFGRP.PxINT bit in the interrupt handler first. It helps minimize the handler codes for finding the port that has generated an interrupt. If this bit is set to 1, an interrupt has occurred in the port group. Next, check the PxINTF.PxIFy bit set to 1 in the port group to determine the port that has generated an interrupt. Clearing the PxINTF.PxIFy bit also clears the PINTFGRP.PxINT bit. If the port is set to interrupt disabled status by the PxINTCTL.PxIEy bit, the PINTFGRP.PxINT bit will not be set even if the PxINTF.PxIFy bit is set to 1.

## 6.6 Control Registers

This section describes the same control registers of all port groups as a single register. For the register and bit configurations in each port group and their initial values, refer to “Control Register and Port Function Configuration of this IC.”

### Px Port Data Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxDAT	15–8	PxOUT[7:0]	0x00	H0	R/W	–
	7–0	PxIN[7:0]	0x00	H0	R	

\*1: This register is effective when the GPIO function is selected.

\*2: The bit configuration differs depending on the port group.

\*3: The initial value may be changed by the port.

#### Bits 15–8 PxOUT[7:0]

These bits are used to set data to be output from the GPIO port pins.

1 (R/W): Output high level from the port pin

0 (R/W): Output low level from the port pin

When output is enabled (PxIOEN.PxOENy bit = 1), the port pin outputs the data set here. Although data can be written when output is disabled (PxIOEN.PxOENy bit = 0), it does not affect the pin status. These bits do not affect the outputs when the port is used as a peripheral I/O function.

#### Bits 7–0 PxIN[7:0]

The GPIO port pin status can be read out from these bits.

1 (R): Port pin = High level

0 (R): Port pin = Low level

The port pin status can be read out when input is enabled (PxIOEN.PxIENy bit = 1). When input is disabled (PxIOEN.PxIENy bit = 0), these bits are always read as 0.

When the port is used for a peripheral I/O function, the input value cannot be read out from these bits.

### Px Port Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxIOEN	15–8	PxIEN[7:0]	0x00	H0	R/W	–
	7–0	PxOEN[7:0]	0x00	H0	R/W	

\*1: This register is effective when the GPIO function is selected.

\*2: The bit configuration differs depending on the port group.

#### Bits 15–8 PxIEN[7:0]

These bits enable/disable the GPIO port input.

1 (R/W): Enable (The port pin status is input.)

0 (R/W): Disable (Input data is fixed at 0.)

When both data output and data input are enabled, the pin output status controlled by this IC can be read.

These bits do not affect the input control when the port is used as a peripheral I/O function.

#### Bits 7–0 PxOEN[7:0]

These bits enable/disable the GPIO port output.

1 (R/W): Enable (Data is output from the port pin.)

0 (R/W): Disable (The port is placed into Hi-Z.)

These bits do not affect the output control when the port is used as a peripheral I/O function.

### Px Port Pull-up/down Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxRCTL	15–8	PxPDPU[7:0]	0x00	H0	R/W	–
	7–0	PxREN[7:0]	0x00	H0	R/W	

\*1: This register is effective when the GPIO function is selected.

\*2: The bit configuration differs depending on the port group.

#### Bits 15–8 PxPDPU[7:0]

These bits select either the pull-up resistor or the pull-down resistor when using a resistor built into the port.

1 (R/W): Pull-up resistor

0 (R/W): Pull-down resistor

The selected pull-up/down resistor is enabled when the PxRCTL.PxRENY bit = 1.

#### Bits 7–0 PxREN[7:0]

These bits enable/disable the port pull-up/down control.

1 (R/W): Enable (The built-in pull-up/down resistor is used.)

0 (R/W): Disable (No pull-up/down control is performed.)

Enabling this function pulls up or down the port when output is disabled (PxIOEN.PxOENy bit = 0). When output is enabled (PxIOEN.PxOENy bit = 1), the PxRCTL.PxRENY bit setting is ineffective regardless of how the PxIOEN.PxIENy bit is set and the port is not pulled up/down.

These bits do not affect the pull-up/down control when the port is used as a peripheral I/O function.

## Px Port Interrupt Flag Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxINTF	15–8	–	0x00	–	R	–
	7–0	PxIF[7:0]	0x00	H0	R/W	Cleared by writing 1.

\*1: This register is effective when the GPIO function is selected.

\*2: The bit configuration differs depending on the port group.

### Bits 15–8 Reserved

### Bits 7–0 PxIF[7:0]

These bits indicate the port input interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

## Px Port Interrupt Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxINTCTL	15–8	PxEDGE[7:0]	0x00	H0	R/W	–
	7–0	PxIE[7:0]	0x00	H0	R/W	–

\*1: This register is effective when the GPIO function is selected.

\*2: The bit configuration differs depending on the port group.

### Bits 15–8 PxEDGE[7:0]

These bits select the input signal edge to generate a port input interrupt.

1 (R/W): An interrupt will occur at a falling edge.

0 (R/W): An interrupt will occur at a rising edge.

### Bits 7–0 PxIE[7:0]

These bits enable port input interrupts.

1 (R/W): Enable interrupts

0 (R/W): Disable interrupts

**Note:** To prevent generating unnecessary interrupts, the corresponding interrupt flag should be cleared before enabling interrupts.

## Px Port Chattering Filter Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxCHATEN	15–8	–	0x00	–	R	–
	7–0	PxCHATEN[7:0]	0x00	H0	R/W	–

\*1: The bit configuration differs depending on the port group.

### Bits 15–8 Reserved

### Bits 7–0 PxCHATEN[7:0]

These bits enable/disable the chattering filter function.

1 (R/W): Enable (The chattering filter is used.)

0 (R/W): Disable (The chattering filter is bypassed.)

## Px Port Mode Select Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxMODESEL	15–8	–	0x00	–	R	–
	7–0	PxSEL[7:0]	0x00	H0	R/W	–

\*1: The bit configuration differs depending on the port group.

\*2: The initial value may be changed by the port.

### Bits 15–8 Reserved

**Bits 7–0 PxSEL[7:0]**

These bits select whether each port is used for the GPIO function or a peripheral I/O function.

1 (R/W): Use peripheral I/O function

0 (R/W): Use GPIO function

**Px Port Function Select Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PxFNCSEL	15–14	Px7MUX[1:0]	0x0	H0	R/W	–
	13–12	Px6MUX[1:0]	0x0	H0	R/W	
	11–10	Px5MUX[1:0]	0x0	H0	R/W	
	9–8	Px4MUX[1:0]	0x0	H0	R/W	
	7–6	Px3MUX[1:0]	0x0	H0	R/W	
	5–4	Px2MUX[1:0]	0x0	H0	R/W	
	3–2	Px1MUX[1:0]	0x0	H0	R/W	
	1–0	Px0MUX[1:0]	0x0	H0	R/W	

\*1: The bit configuration differs depending on the port group.

\*2: The initial value may be changed by the port.

**Bits 15–14 Px7MUX[1:0]**

: :

**Bits 1–0 Px0MUX[1:0]**

These bits select the peripheral I/O function to be assigned to each port pin.

Table 6.6.1 Selecting Peripheral I/O Function

PxFNCSEL.PxyMUX[1:0] bits	Peripheral I/O function
0x3	Function 3
0x2	Function 2
0x1	Function 1
0x0	Function 0

This selection takes effect when the PxMODSEL.PxSELY bit = 1.

**P Port Clock Control Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
PCLK	15–9	–	0x00	–	R	–
	8	DBRUN	0	H0	R/WP	
	7–4	CLKDIV[3:0]	0x0	H0	R/WP	
	3–2	KRSTCFG[1:0]	0x0	H0	R/WP	
	1–0	CLKSRC[1:0]	0x0	H0	R/WP	

**Bits 15–9 Reserved****Bit 8 DBRUN**

This bit sets whether the PPORT operating clock is supplied in DEBUG mode or not.

1 (R/WP): Clock supplied in DEBUG mode

0 (R/WP): No clock supplied in DEBUG mode

**Bits 7–4 CLKDIV[3:0]**

These bits select the division ratio of the PPORT operating clock (chattering filter clock).

**Bits 3–2 KRSTCFG[1:0]**

These bits configure the key-entry reset function.

Table 6.6.2 Key-Entry Reset Function Settings

PCLK.KRSTCFG[1:0] bits	key-entry reset
0x3	Reset when P0[3:0] inputs = all low
0x2	Reset when P0[2:0] inputs = all low
0x1	Reset when P0[1:0] inputs = all low
0x0	Disable

## 6 I/O PORTS (PPORT)

### Bits 1–0 CLKSRC[1:0]

These bits select the clock source of PPORT (chattering filter).

The PPORT operating clock should be configured by selecting the clock source using the PCLK.CLKSRC[1:0] bits and the clock division ratio using the PCLK.CLKDIV[3:0] bits as shown in Table 6.6.3. These settings determine the input sampling time of the chattering filter.

Table 6.6.3 Clock Source and Division Ratio Settings

\*1: Only the bits corresponding to the port groups that support interrupts are provided.

#### Bits 15–13 Reserved

#### Bits 12–0 PxINT

These bits indicate that Px port group includes a port that has generated an interrupt.

1 (R): A port generated an interrupt

0 (R): No port generated an interrupt

The PINTFGRP.PxINT bit is cleared when the interrupt flag for the port that has generated an interrupt is cleared.

## 6.7 Control Register and Port Function Configuration of this IC

This section shows the PPORT control register/bit configuration in this IC and the list of peripheral I/O functions selectable for each port.

### 6.7.6 Pd Port Group

The Pd port group consists of five ports Pd0–Pd4 and three ports Pd0–Pd2 are configured as a debugging function port at initialization. These five ports support the GPIO function. The GPIO function of the Pd2 port supports output only, therefore, the pull-up/down function cannot be used.

**Note:** The Pd3–Pd4 ports do not exist in the 32-pin package.

# 7 Universal Port Multiplexer (UPMUX)

## 7.1 Overview

UPMUX is a multiplexer that allows software to assign the desired peripheral I/O function to an I/O port. The main features are outlined below.

- Allows programmable assignment of the synchronous serial interface, I<sup>2</sup>C, UART, and 16-bit PWM timer peripheral I/O functions to the P0, P1, P2, and P3 ports.
- The peripheral I/O function assigned via UPMUX is enabled by setting the P<sub>x</sub>FNCSEL.P<sub>xy</sub>MUX[1:0] bits to 0x1.

**Note:** 'x', which is used in the port names P<sub>xy</sub>, register names, and bit names, refers to a port group (x = 0, 1, 2, 3) and 'y' refers to a port number (y = 0, 1, 2, ..., 7).

Figure 7.1.1 shows the configuration of UPMUX.

Figure 7.1.1 UPMUX Configuration

## 7.2 Peripheral Circuit I/O Function Assignment

An I/O function of a peripheral circuit supported may be assigned to peripheral I/O function 1 of an I/O port listed above. The following shows the procedure to assign a peripheral I/O function and enable it in the I/O port:

1. Configure the P<sub>x</sub>IOEN register of the I/O port.
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>IEN<sub>y</sub> bit to 0. (Disable input)
  - Set the P<sub>x</sub>IOEN.P<sub>x</sub>OEN<sub>y</sub> bit to 0. (Disable output)
2. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit of the I/O port to 0. (Disable peripheral I/O function)
3. Set the following P<sub>x</sub>UPMUX<sub>n</sub> register bits (n = 0 to 3).
  - P<sub>x</sub>UPMUX<sub>n</sub>.P<sub>xy</sub>PERISEL[2:0] bits (Select peripheral circuit)
  - P<sub>x</sub>UPMUX<sub>n</sub>.P<sub>xy</sub>PERICH[1:0] bits (Select peripheral circuit channel)
  - P<sub>x</sub>UPMUX<sub>n</sub>.P<sub>xy</sub>PPFNC[2:0] bits (Select function to assign)
4. Initialize the peripheral circuit.
5. Set the P<sub>x</sub>FNCSEL.P<sub>xy</sub>MUX[1:0] bits of the I/O port to 0x1. (Select peripheral I/O function 1)
6. Set the P<sub>x</sub>MODESEL.P<sub>x</sub>SEL<sub>y</sub> bit of the I/O port to 1. (Enable peripheral I/O function)

\*1: 'x' in the register name refers to a port group number and 'n' refers to a register number (0–3).

\*2: 'x' in the bit name refers to a port group number, 'y' refers to an even port number (0, 2, 4, 6), and "z" refers to an odd port number (z = y + 1).

#### Bits 15–13 PxzPPFNC[2:0]

#### Bits 7–5 PxyPPFNC[2:0]

These bits specify the peripheral I/O function to be assigned to the port. (See Table 7.3.1.)

#### Bits 12–11 PxzPERICH[1:0]

#### Bits 4–3 PxyPERICH[1:0]

These bits specify a peripheral circuit channel number. (See Table 7.3.1.)

#### Bits 10–8 PxzPERISEL[2:0]

#### Bits 2–0 PxyPERISEL[2:0]

These bits specify a peripheral circuit. (See Table 7.3.1.)

\* "None" means no assignment. Selecting this will put the Pxy pin into Hi-Z status when peripheral I/O function 1 is selected and enabled in the I/O port.

**Note:** Do not assign a peripheral input function to two or more I/O ports. Although the I/O ports output the same waveforms when an output function is assigned to two or more I/O port, a skew occurs due to the internal delay.

# 8 Watchdog Timer (WDT)

## 8.1 Overview

WDT restarts the system if a problem occurs, such as when the program cannot be executed normally.

The features of WDT are listed below.

- Includes a 10-bit up counter to count NMI/reset generation cycle.
- A counter clock source and clock division ratio are selectable.
- Counter overflow generates a reset or NMI.

Figure 8.1.1 shows the configuration of WDT.

Figure 8.1.1 WDT Configuration

## 8.2 Clock Settings

### 8.2.1 WDT Operating Clock

When using WDT, the WDT operating clock CLK\_WDT must be supplied to WDT from the clock generator.

The CLK\_WDT supply should be controlled as in the procedure shown below.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
3. Set the following WDTCLK register bits:
 

WDTCLK.CLKSRC[1:0] bits	(Clock source selection)
WDTCLK.CLKDIV[1:0] bits	(Clock division ratio selection = Clock frequency setting)
4. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

Use the following equation to calculate the WDT counter overflow cycle (NMI/reset generation cycle).

$$t_{\text{WDT}} = \frac{1,024}{\text{CLK\_WDT}} \quad (\text{Eq. 8.1})$$

Where

t<sub>WDT</sub>: Counter overflow cycle [second]  
 CLK\_WDT: WDT operating clock frequency [Hz]

Example) t<sub>WDT</sub> = 4 seconds when CLK\_WDT = 256 Hz

## 8.2.2 Clock Supply in DEBUG Mode

The CLK\_WDT supply during DEBUG mode should be controlled using the WDTCLK.DBRUN bit.

The CLK\_WDT supply to WDT is suspended when the CPU enters DEBUG mode if the WDTCLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_WDT supply resumes. Although WDT stops operating when the CLK\_WDT supply is suspended, the register retains the status before DEBUG mode was entered.

If the WDTCLK.DBRUN bit = 1, the CLK\_WDT supply is not suspended and WDT will keep operating in DEBUG mode.

## 8.3 Operations

---

### 8.3.1 WDT Control

#### Starting up WDT

WDT should be initialized and started up with the procedure listed below.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Configure the WDT operating clock.
3. Configure the WDTCTL.NMIXRST bit. (Select NMI or reset mode)
4. Write 1 to the WDTCTL.WDTCNTRST bit. (Reset WDT counter)
5. Write a value other than 0xa to the WDTCTL.WDTRUN[3:0] bits. (Start up WDT)
6. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

#### Resetting WDT

WDT generates a system reset (WDTCTL.NMIXRST bit = 0) or NMI (WDTCTL.NMIXRST bit = 1) when the counter overflows. To avert system restart by WDT, its embedded counter must be reset periodically via software while WDT is running.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Write 1 to the WDTCTL.WDTCNTRST bit. (Reset WDT counter)
3. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

A location should be provided for periodically processing this routine. Process this routine within the twdt cycle. After resetting, WDT starts counting with a new NMI/reset generation cycle.

If WDT is not reset within the twdt cycle for any reason, the CPU is switched to interrupt processing by NMI or reset, the interrupt vector is read out, and the interrupt handler routine is executed.

If the counter overflows and generates an NMI without WDT being reset, the WDTCTL.STATNMI bit is set to 1.

### 8.3.2 Operations in HALT and SLEEP Modes

#### During HALT mode

WDT operates in HALT mode. HALT mode is therefore cleared by an NMI or reset if it continues for more than the NMI/reset generation cycle and the NMI or reset handler is executed. To disable WDT in HALT mode, stop WDT by writing 0xa to the WDTCTL.WDTRUN[3:0] bits before executing the halt instruction. Reset WDT before resuming operations after HALT mode is cleared.

#### During SLEEP mode

WDT operates in SLEEP mode if the selected clock source is running. In this case SLEEP mode is cleared by an NMI or reset if it continues for more than the NMI/reset generation cycle and the NMI or reset handler is executed. Therefore, stop WDT by setting the WDTCTL.WDTRUN[3:0] bits before executing the slp instruction.

If the clock source stops in SLEEP mode, WDT stops. To prevent generation of an unnecessary NMI or reset after clearing SLEEP mode, reset WDT before executing the slp instruction. WDT should also be stopped as required using the WDTCTL.WDTRUN[3:0] bits.

## 8.4 Control Registers

### WDT Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
WDTCLK	15–9	–	0x00	–	R	–
	8	DBRUN	0	H0	R/WP	
	7–6	–	0x0	–	R	
	5–4	CLKDIV[1:0]	0x0	H0	R/WP	
	3–2	–	0x0	–	R	
	1–0	CLKSRC[1:0]	0x0	H0	R/WP	

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the WDT operating clock is supplied in DEBUG mode or not.

1 (R/WP): Clock supplied in DEBUG mode

0 (R/WP): No clock supplied in DEBUG mode

**Bits 7–6 Reserved**

**Bits 5–4 CLKDIV[1:0]**

These bits select the division ratio of the WDT operating clock (counter clock). The clock frequency should be set to around 256 Hz.

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of WDT.

Table 8.4.1 Clock Source and Division Ratio Settings

WDTCLK. CLKDIV[1:0] bits	WDTCLK.CLKSRC[1:0] bits			
	0x0	0x1	0x2	0x3
	IOSC	OSC1	OSC3	EXOSC
0x3	1/16,384	1/128	1/16,384	1/1
0x2	1/8,192		1/8,192	
0x1	1/4,096		1/4,096	
0x0	1/2,048		1/2,048	

(Note) The oscillation circuits/external input that are not supported in this IC cannot be selected as the clock source.

### WDT Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
WDTCTL	15–10	–	0x00	–	R	–
	9	NMIXRST	0	H0	R/WP	
	8	STATNMI	0	H0	R	
	7–5	–	0x0	–	R	
	4	WDTCTRST	0	H0	WP	Always read as 0.
	3–0	WDTRUN[3:0]	0xa	H0	R/WP	–

**Bits 15–10 Reserved**

**Bit 9 NMIXRST**

This bit sets the WDT operating mode.

1 (R/WP): NMI mode

0 (R/WP): Reset mode

This bit is used to select whether an NMI signal or a reset signal is output when WDT has not been reset within the NMI/reset generation cycle.

## 8 WATCHDOG TIMER (WDT)

### Bit 8 STATNMI

This bit indicates that a counter overflow and NMI have occurred.

1 (R): NMI (counter overflow) occurred

0 (R): NMI not occurred

When the NMI generation function of WDT is used, read this bit in the NMI handler routine to confirm that WDT was the source of the NMI.

The STATNMI set to 1 is cleared to 0 by resetting WDT.

### Bits 7–5 Reserved

### Bit 4 WDCNTRST

This bit resets WDT.

1 (WP): Reset

0 (WP): Ignored

0 (R): Always 0 when being read

### Bits 3–0 WDTRUN[3:0]

These bits control WDT to run and stop.

0xa (R/WP): Stop

Values other than 0xa (R/WP): Run

Always 0x0 is read if a value other than 0xa is written.

Since an NMI or reset may be generated immediately after running depending on the counter value, WDT should also be reset concurrently when running WDT.

# 9 Real-Time Clock (RTCA)

## 9.1 Overview

RTCA is a real-time clock with a perpetual calendar function. The main features of RTCA are outlined below.

- Includes a BCD real-time clock counter to implement a time-of-day clock (second, minute, and hour) and calendar (day, day of the week, month, and year with leap year supported).
- Provides a hold function for reading correct counter values by suspending the real-time clock counter operation.
- 24-hour or 12-hour mode is selectable.
- Capable of controlling the starting and stopping of the time-of-day clock.
- Provides a 30-second correction function to adjust time using a time signal.
- Includes a 1 Hz counter to count 128 to 1 Hz.
- Includes a BCD stopwatch counter with 1/100-second counting supported.
- Provides a theoretical regulation function to correct clock error due to frequency tolerance with no external parts required.

Figure 9.1.1 shows the configuration of RTCA.

Figure 9.1.1 RTCA Configuration

## 9.2 Output Pin and External Connection

### 9.2.1 Output Pin

Table 9.2.1.1 shows the RTCA pin.

Table 9.2.1.1 RTCA Pin

Pin name	I/O*	Initial status*	Function
RTC1S	O	O (L)	1-second signal monitor output pin

\* Indicates the status when the pin is configured for RTCA.

If the port is shared with the RTCA output function and other functions, the RTCA function must be assigned to the port. For more information, refer to the “I/O Ports” chapter.

## 9.3 Clock Settings

### 9.3.1 RTCA Operating Clock

RTCA uses CLK\_RTCA, which is generated by the clock generator from OSC1 as the clock source, as its operating clock. RTCA is operable when OSC1 is enabled.

To continue the RTCA operation during SLEEP mode with OSC1 being activated, the CLGOSC.OSC1SLPC bit must be set to 0.

### 9.3.2 Theoretical Regulation Function

The time-of-day clock loses accuracy if the OSC1 frequency  $f_{osc1}$  has a frequency tolerance from 32.768 kHz. To correct this error without changing any external part, RTCA provides a theoretical regulation function. Follow the procedure below to perform theoretical regulation.

1. Measure the frequency tolerance “m [ppm]” of  $f_{osc1}$ .
2. Determine the theoretical regulation execution cycle time “n seconds.”
3. Determine the value to be written to the RTCCTL.RTCTRM[6:0] bits from the results in Steps 1 and 2.
4. Write the value determined in Step 3 to the RTCCTL.RTCTRM[6:0] bits periodically in n-second cycles using an RTCA alarm or second interrupt.
5. Monitor the RTC1S signal to check that every n-second cycle has no error included.

The correction value for theoretical regulation can be specified within the range from -64 to +63 and it should be written to the RTCCTL.RTCTRM[6:0] bits as a two’s-complement number. Use Eq. 9.1 to calculate the correction value.

$$RTCTRM[6:0] = \frac{m}{10^6} \times 256 \times n \quad (\text{However, RTCTRM[6:0] is an integer after rounding off to -64 to +63.}) \quad (\text{Eq. 9.1})$$

Where

- n: Theoretical regulation execution cycle time [second] (time interval to write the correct value to the RTCCTL.RTCTRM[6:0] bits periodically via software)
- m: OSC1 frequency tolerance [ppm]

Figure 9.3.2.1 shows the RTC1S signal waveform.

Figure 9.3.2.1 RTC1S Signal Waveform

Table 9.3.2.1 lists the frequency tolerance correction rates when the theoretical regulation execution cycle time n is 4,096 seconds as an example.

Table 9.3.2.1 Correction Rates when Theoretical Regulation Execution Cycle Time n = 4,096 Seconds

RTCCTL.RTCTRM[6:0] bits (two's-complement)	Correction value (decimal)	Correction rate [ppm]	RTCCTL.RTCTRM[6:0] bits (two's-complement)	Correction value (decimal)	Correction rate [ppm]
0x00	0	0.0	0x40	-64	-61.0
0x01	1	1.0	0x41	-63	-60.1
0x02	2	1.9	0x42	-62	-59.1
0x03	3	2.9	0x43	-61	-58.2
...	...	...	...	...	...
0x3e	62	59.1	0x7e	-2	-1.9
0x3f	63	60.1	0x7f	-1	-1.0

Minimum resolution: 1 ppm, Correction rate range: -61.0 to 60.1 ppm

- Notes:**
- The theoretical regulation affects only the real-time clock counter and 1 Hz counter. It does not affect the stopwatch counter.
  - After a value is written to the RTCCTL.RTCTRM[6:0] bits, the theoretical regulation correction takes effect on the 1 Hz counter value at the same timing as when the 1 Hz counter changes to 0x7f. Also an interrupt occurs depending on the counter value at this time.

## 9.4 Operations

---

### 9.4.1 RTCA Control

Follow the sequences shown below to set time to RTCA, to read the current time and to set alarm.

#### Time setting

1. Set RTCA to 12H or 24H mode using the RTCCTL.RTC24H bit.
2. Write 1 to the RTCCTL.RTCRUN bit to enable for the real-time clock counter to start counting up.
3. Check to see if the RTCCTL.RTCBSY bit = 0 that indicates the counter is ready to rewrite. If the RTCCTL.RTCBSY bit = 1, wait until it is set to 0.
4. Write the current date and time in BCD code to the control bits listed below.
  - RTCSEC.RTCSH[2:0]/RTCSL[3:0] bits (second)
  - RTCHUR.RTCMIH[2:0]/RTCMIL[3:0] bits (minute)
  - RTCHUR.RTCHH[1:0]/RTCHL[3:0] bits (hour)
  - RTCHUR.RTCAP bit (AM/PM) (effective when RTCCTL.RTC24H bit = 0)
  - RTCMON.RTCDH[1:0]/RTCDL[3:0] bits (day)
  - RTCMON.RTCMOH/RTCMOL[3:0] bits (month)
  - RTCYAR.RTCYH[3:0]/RTCYL[3:0] bits (year)
  - RTCYAR.RTCWK[2:0] bits (day of the week)
5. Write 1 to the RTCCTL.RTCADJ bit (execute 30-second correction) using a time signal to adjust the time. (For more information on the 30-second correction, refer to “Real-Time Clock Counter Operations.”)
6. Write 1 to the real-time clock counter interrupt flags in the RTCINTF register to clear them.
7. Write 1 to the interrupt enable bits in the RTCINTE register to enable real-time clock counter interrupts.

#### Time read

1. Check to see if the RTCCTL.RTCBSY bit = 0. If the RTCCTL.RTCBSY bit = 1, wait until it is set to 0.
2. Write 1 to the RTCCTL.RTCHLD bit to suspend count-up operation of the real-time clock counter.
3. Read the date and time from the control bits listed in “Time setting, Step 4” above.
4. Write 0 to the RTCCTL.RTCHLD bit to resume count-up operation of the real-time clock counter. If a second count-up timing has occurred in the count hold state, the hardware corrects the second counter for +1 second (for more information on the +1 second correction, refer to “Real-Time Clock Counter Operations”).

#### Alarm setting

1. Write 0 to the RTCINTE.ALARMIE bit to 0 to disable alarm interrupts.
2. Write the alarm time in BCD code to the control bits listed below (a time within 24 hours from the current time can be specified).
  - RTCALM1.RTCSHA[2:0]/RTCSLA[3:0] bits (second)
  - RTCALM2.RTCMIHA[2:0]/RTCMILA[3:0] bits (minute)
  - RTCALM2.RTCHHA[1:0]/RTCHLA[3:0] bits (hour)
  - RTCALM2.RTCAPA bit (AM/PM) (effective when RTCCTL.RTC24H bit = 0)
3. Write 1 to the RTCINTF.ALARMIF bit to clear the alarm interrupt flag.
4. Write 1 to the RTCINTE.ALARMIE bit to enable alarm interrupts.
 

When the real-time clock counter reaches the alarm time set in Step 2, an alarm interrupt occurs.

## 9.4.2 Real-Time Clock Counter Operations

The real-time clock counter consists of second, minute, hour, AM/PM, day, month, year, and day of the week counters and it performs counting up using the RTC1S signal. It has the following functions as well.

### Recognizing leap years

The leap year recognizing algorithm used in RTCA is effective only for Christian Era years. Years within 0 to 99 that can be divided by four without a remainder are recognized as leap years. If the year counter = 0x00, RTCA assumes it as a common year. If a leap year is recognized, the count range of the day counter changes when the month counter is set to February.

### Corrective operation when a value out of the effective range is set

When a value out of the effective range is set to the year, day of the week, or hour (in 24H mode) counter, the counter will be cleared to 0 at the next count-up timing. When a such value is set to the month, day, or hour (in 12H mode) counter, the counter will be set to 1 at the next count-up timing.

### 30-second correction

This function is provided to set the time-of-day clock by the time signal. Writing 1 to the RTCCTL.RTCADJ bit adds 1 to the minute counter if the second counter represents 30 to 59 seconds, or clears the second counter with the minute counter left unchanged if the second counter represents 0 to 29 seconds.

### +1 second correction

If a second count-up timing occurred while the RTCCTL.RTCHLD bit = 1 (count hold state), the real-time clock counter counts up by +1 second (performs +1 second correction) after the counting has resumed by writing 0 to the RTCCTL.RTCHLD bit.

**Note:** If two or more second count-up timings occurred while the RTCCTL.RTCHLD bit = 1, the counter is always corrected for +1 second only.

## 9.4.3 Stopwatch Control

Follow the sequences shown below to start counting of the stopwatch and to read the counter.

### Count start

1. Write 1 to the RTCSWCTL.SWRST bit to reset the stopwatch counter.
2. Write 1 to the stopwatch interrupt flags in the RTCINTF register to clear them.
3. Write 1 to the interrupt enable bits in the RTCINTE register to enable stopwatch interrupts.
4. Write 1 to the RTCSWCTL.SWRUN bit to start stopwatch count up operation.

### Counter read

1. Read the count value from the RTCSWCTL.BCD10[3:0] and BCD100[3:0] bits.
2. Read again.
  - i. If the two read values are the same, assume that the count values are read correctly.
  - ii. If different values are read, perform reading once more and compare the read value with the previous one.

## 9.4.4 Stopwatch Count-up Pattern

The stopwatch consists of 1/100-second and 1/10-second counters and these counters perform counting up in increments of approximate 1/100 and 1/10 seconds with the count-up patterns shown in Figure 9.4.4.1.

Figure 9.4.4.1 Stopwatch Count-Up Patterns

## 9.5 Interrupts

RTCA has a function to generate the interrupts shown in Table 9.5.1.

Table 9.5.1 RTCA Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Alarm	RTCINTF.ALARMIF	Matching between the RTCALM1–2 register contents and the real-time clock counter contents	Writing 1

Figure 9.5.1 RTCA Interrupt Timings

- Notes:**
- 1-second to 1/32-second interrupts occur after a lapse of 1/256 second from change of the 1 Hz counter value.
  - An alarm interrupt occurs after a lapse of 1/256 second from matching between the AM/PM (in 12H mode), hour, minute, and second counter value and the alarm setting value.

RTCA provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 9.6 Control Registers

### RTC Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RTCCTL	15	RTCTRMBSY	0	H0	R	–
	14–8	RTCTRM[6:0]	0x00	H0	W	Read as 0x00.
	7	–	0	–	R	–
	6	RTCBSY	0	H0	R	–
	5	RTCHLD	0	H0	R/W	Cleared by setting the RTCCTL.RTCRST bit to 1.
	4	RTC24H	0	H0	R/W	–
	3	–	0	–	R	–
	2	RTCADJ	0	H0	R/W	Cleared by setting the RTCCTL.RTCRST bit to 1.
	1	RTCST	0	H0	R/W	–
0	RTCUN	0	H0	R/W	–	

#### Bit 15 RTCTRMBSY

This bit indicates whether the theoretical regulation is currently executed or not.

1 (R): Theoretical regulation is executing.

0 (R): Theoretical regulation has finished (or not executed).

This bit goes 1 when a value is written to the RTCCTL.RTCTRM[6:0] bits. The theoretical regulation takes up to 1 second for execution. This bit reverts to 0 automatically after the theoretical regulation has finished execution.

#### Bits 14–8 RTCTRM[6:0]

Write the correction value for adjusting the 1 Hz frequency to these bits to execute theoretical regulation. For a calculation method of correction value, refer to “Theoretical Regulation Function.”

**Note:** When the RTCCTL.RTCTRMBSY bit = 1, the RTCCTL.RTCTRM[6:0] bits cannot be rewritten.

#### Bit 7 Reserved

#### Bit 6 RTCBSY

This bit indicates whether the counter is performing count-up operation or not.

1 (R): In count-up operation

0 (R): Idle (ready to rewrite real-time clock counter)

This bit goes 1 when performing 1-second count-up, +1 second correction, or 30-second correction. It retains 1 for 1/256 second and then reverts to 0.

#### Bit 5 RTCHLD

This bit halts the count-up operation of the real-time clock counter.

1 (R/W): Halt real-time clock counter count-up operation

0 (R/W): Normal operation

Writing 1 to this bit halts the count-up operation of the real-time clock counter, this makes it possible to read the counter value correctly without changing the counter. Write 0 to this bit to resume count-up operation immediately after the counter has been read. Depending on these operation timings, the +1 second correction may be executed after the count-up operation resumes. For more information on the +1 second correction, refer to “Real-Time Clock Counter Operations.”

**Note:** When the RTCCTL.RTCTRMBSY bit = 1, the RTCCTL.RTCHLD bit cannot be rewritten to 1 (as fixed at 0).

**Bit 4 RTC24H**

This bit sets the hour counter to 24H mode or 12H mode.

1 (R/W): 24H mode

0 (R/W): 12H mode

This selection changes the count range of the hour counter. Note, however, that the counter value is not updated automatically, therefore, it must be programmed again.

**Note:** Be sure to avoid writing to this bit when the RTCCTL.RTCRUN bit = 1.

**Bit 3 Reserved****Bit 2 RTCADJ**

This bit executes the 30-second correction time adjustment function.

1 (W): Execute 30-second correction

0 (W): Ineffective

1 (R): 30-second correction is executing.

0 (R): 30-second correction has finished. (Normal operation)

Writing 1 to this bit executes 30-second correction and an enabled interrupt occurs even if the RTCCTL.RTCRUN bit = 0. The correction takes up to 2/256 seconds. The RTCCTL.RTCADJ bit is automatically cleared to 0 when the correction has finished. For more information on the 30-second correction, refer to “Real-Time Clock Counter Operations.”

**Notes:**

- Be sure to avoid writing to this bit when the RTCCTL.RTCBSY bit = 1.
- Do not write 1 to this bit again while the RTCCTL.RTCADJ bit = 1.

**Bit 1 RTCRST**

This bit resets the 1 Hz counter, the RTCCTL.RTCADJ bit, and the RTCCTL.RTCHLD bit.

1 (W): Reset

0 (W): Ineffective

1 (R): Reset is being executed.

0 (R): Reset has finished. (Normal operation)

This bit is automatically cleared to 0 after reset has finished.

**Bit 0 RTCRUN**

This bit starts/stops the real-time clock counter.

1 (R/W): Running/start control

0 (R/W): Idle/stop control

When the real-time clock counter stops counting by writing 0 to this bit, the counter retains the value when it stopped. Writing 1 to this bit again resumes counting from the value retained.

**RTC Second Alarm Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RTCALM1	15	–	0	–	R	–
	14–12	RTCASHA[2:0]	0x0	H0	R/W

	7–0	–	0x00	–	R	

**Bit 15 Reserved****Bits 14–12 RTCASHA[2:0]****Bits 11–8 RTCSLA[3:0]**

The RTCALM1.RTCASHA[2:0] bits and the RTCALM1.RTCSLA[3:0] bits set the 10-second digit and 1-second digit of the alarm time, respectively. A value within 0 to 59 seconds can be set in BCD code as shown in Table 9.6.1.

## 9 REAL-TIME CLOCK (RTCA)

Table 9.6.1 Setting Examples in BCD Code

### RTC Hour/Minute Alarm Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RTCALM2	15	–	0	–	R	–
	14	RTCAPA	0	H0	R/W	
	13–12	RTCHHA[1:0]	0x0	H0	R/W	
	11–8	RTCHLA[3:0]	0x0	H0	R/W	
	7	–	0	–	R	
	6–4	RTCMIHA[2:0]	0x0	H0	R/W	
	3–0	RTCMILA[3:0]	0x0	H0	R/W	

**Bit 15** Reserved

**Bit 14** **RTCAPA**

This bit sets A.M. or P.M. of the alarm time in 12H mode (RTCCTL.RTC24H bit = 0).

1 (R/W): P.M.

0 (R/W): A.M.

This setting is ineffective in 24H mode (RTCCTL.RTC24H bit = 1).

**Bits 13–12** **RTCHHA[1:0]**

**Bits 11–8** **RTCHLA[3:0]**

The RTCALM2.RTCHHA[1:0] bits and the RTCALM2.RTCHLA[3:0] bits set the 10-hour digit and 1-hour digit of the alarm time, respectively. A value within 1 to 12 o'clock in 12H mode or 0 to 23 in 24H mode can be set in BCD code.

**Bit 7** Reserved

**Bits 6–4** **RTCMIHA[2:0]**

**Bits 3–0** **RTCMILA[3:0]**

The RTCALM2.RTCMIHA[2:0] bits and the RTCALM2.RTCMILA[3:0] bits set the 10-minute digit and 1-minute digit of the alarm time, respectively. A value within 0 to 59 minutes can be set in BCD code.

### RTC Stopwatch Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RTCSWCTL	15–12	BCD10[3:0]	0x0	H0	R	–
	11–8	BCD100[3:0]	0x0	H0	R	
	7–5	–	0x0	–	R	
	4	SWRST	0	H0	W	Read as 0.
	3–1	–	0x0	–	R	–
	0	SWRUN	0	H0	R/W	

**Bits 15–12** **BCD10[3:0]**

**Bits 11–8** **BCD100[3:0]**

The 1/10-second and 1/100-second digits of the stopwatch counter can be read as a BCD code from the RTCSWCTL.BCD10[3:0] bits and the RTCSWCTL.BCD100[3:0] bits, respectively.

**Note:** The counter value may not be read correctly while the stopwatch counter is running. The RTCSWCTL.BCD10[3:0]/BCD100[3:0] bits must be read twice and assume the counter value was read successfully if the two read results are the same.

**Bits 7–5 Reserved**

**Bit 4 SWRST**

This bit resets the stopwatch counter to 0x00.

1 (W): Reset

0 (W): Ineffective

0 (R): Always 0 when being read

When the stopwatch counter in running status is reset, it continues counting from count 0x00. The stopwatch counter retains 0x00 if it is reset in idle status.

**Bits 3–1 Reserved**

**Bit 0 SWRUN**

This bit starts/stops the stopwatch counter.

1 (R/W): Running/start control

0 (R/W): Idle/stop control

When the stopwatch counter stops counting by writing 0 to this bit, the counter retains the value when it stopped. Writing 1 to this bit again resumes counting from the value retained.

**Note:** The stopwatch counter stops in sync with the stopwatch clock after 0 is written to the RTCSWCTL.SWRUN bit. Therefore, the counter value may be incremented (+1) from the value at writing 0.

## RTC Second/1Hz Register

0	RTC128HZ	0	H0	R		

**Bit 15 Reserved**

**Bits 14–12 RTCSH[2:0]**

**Bits 11–8 RTCSL[3:0]**

The RTCSEC.RTCSH[2:0] bits and the RTCSEC.RTCSL[3:0] bits are used to set and read the 10-second digit and the 1-second digit of the second counter, respectively. The setting/read values are a BCD code within the range from 0 to 59.

**Note:** Be sure to avoid writing to the RTCSEC.RTCSH[2:0]/RTCSL[3:0] bits while the RTCCTL.RTCBSY bit = 1.

**Bit 15**      **Reserved**

**Bit 14**      **RTCAP**

This bit is used to set and read A.M. or P.M. data in 12H mode (RTCCTL.RTC24H bit = 0).

1 (R/W): P.M.

0 (R/W): A.M.

In 24H mode (RTCCTL.RTC24H bit = 1), this bit is fixed at 0 and writing 1 is ignored. However, if the RTCHUR.RTCAP bit = 1 when changed to 24H mode, it goes 0 at the next count-up timing of the hour counter.

**Bits 13–12** **RTCHH[1:0]**

**Bits 11–8** **RTCHL[3:0]**

The RTCHUR.RTCHH[1:0] bits and the RTCHUR.RTCHL[3:0] bits are used to set and read the 10-hour digit and the 1-hour digit of the hour counter, respectively. The setting/read values are a BCD code within the range from 1 to 12 in 12H mode or 0 to 23 in 24H mode.

**Note:** Be sure to avoid writing to the RTCHUR.RTCHH[1:0]/RTCHL[3:0] bits while the RTCCTL.RTCBSY bit = 1.

**Bit 7**      **Reserved**

# 10 Supply Voltage Detector (SVD)

## 10.1 Overview

SVD is a supply voltage detector to monitor the power supply voltage on the V<sub>DD</sub> pin or the voltage applied to an external pin. The main features are listed below.

- Power supply voltage to be detected: Selectable from V<sub>DD</sub> and an external power supply (EXSVD)
- Detectable voltage level: Selectable from among 30 levels (1.2 to 3.6 V)
- Detection results:
  - Can be read whether the power supply voltage is lower than the detection voltage level or not.
  - Can generate an interrupt or a reset when low power supply voltage is detected.
- Interrupt: 1 system (Low power supply voltage detection interrupt)
- Supports intermittent operations:
  - Three detection cycles are selectable.
  - Low power supply voltage detection count function to generate an interrupt/reset when low power supply voltage is successively detected the number of times specified.
  - Continuous operation is also possible.

Figure 10.1.1 shows the configuration of SVD.

Figure 10.1.1 SVD Configuration

## 10.2 Input Pin and External Connection

### 10.2.1 Input Pin

Table 10.2.1.1 shows the SVD input pin.

Table 10.2.1.1 SVD Input Pin

Pin name	I/O*	Initial status*	Function
EXSVD	A	A (Hi-Z)	External power supply voltage detection pin

\* Indicates the status when the pin is configured for SVD.

If the port is shared with the EXSVD pin and other functions, the EXSVD function must be assigned to the port before SVD can be activated. For more information, refer to the “I/O Ports” chapter.

### 10.2.2 External Connection

Figure 10.2.2.1 Connection between EXSVD Pin and External Power Supply

REXT resistance value must be determined so that it will be sufficiently smaller than the EXSVD input impedance REXSVD. For the EXSVD pin input voltage range and the EXSVD input impedance, refer to “Supply Voltage Detector Characteristics” in the “Electrical Characteristics” chapter.

## 10.3 Clock Settings

### 10.3.1 SVD Operating Clock

When using SVD, the SVD operating clock CLK\_SVD must be supplied to SVD from the clock generator. The CLK\_SVD supply should be controlled as in the procedure shown below.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
3. Set the following SVDCLK register bits:
  - SVDCLK.CLKSRC[1:0] bits (Clock source selection)
  - SVDCLK.CLKDIV[2:0] bits (Clock division ratio selection = Clock frequency setting)
4. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

The CLK\_SVD frequency should be set to around 32 kHz.

### 10.3.2 Clock Supply in SLEEP Mode

When using SVD during SLEEP mode, the SVD operating clock CLK\_SVD must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_SVD clock source.

If the CLGOSC.xxxxSLPC bit for the CLK\_SVD clock source is 1, the CLK\_SVD clock source is deactivated during SLEEP mode and SVD stops with the register settings maintained at those before entering SLEEP mode. After the CPU returns to normal mode, CLK\_SVD is supplied and the SVD operation resumes.

### 10.3.3 Clock Supply in DEBUG Mode

The CLK\_SVD supply during DEBUG mode should be controlled using the SVDCLK.DBRUN bit.

The CLK\_SVD supply to SVD is suspended when the CPU enters DEBUG mode if the SVDCLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_SVD supply resumes. Although SVD stops operating when the CLK\_SVD supply is suspended, the registers retain the status before DEBUG mode was entered.

If the SVDCLK.DBRUN bit = 1, the CLK\_SVD supply is not suspended and SVD will keep operating in DEBUG mode.

## 10.4 Operations

### 10.4.1 SVD Control

#### Starting detection

SVD should be initialized and activated with the procedure listed below.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Configure the operating clock using the SVDCLK.CLKSRC[1:0] and SVDCLK.CLKDIV[2:0] bits.
3. Set the following SVDCTL register bits:
  - SVDCTL.VDSEL bit (Select detection voltage ( $V_{DD}$  or EXSVD))
  - SVDCTL.SVDSC[1:0] bits (Set low power supply voltage detection counter)
  - SVDCTL.SVDC[4:0] bits (Set SVD detection voltage  $V_{SVD}$ )
  - SVDCTL.SVDRE[3:0] bits (Select reset/interrupt mode)
  - SVDCTL.SVDM[1:0] bits (Set intermittent operation mode)
4. Set the following bits when using the interrupt:
  - Write 1 to the SVDINTF.SVDIF bit. (Clear interrupt flag)
  - Set the SVDINTE.SDVIE bit to 1. (Enable SVD interrupt)
5. Set the SVDCTL.MODEN bit to 1. (Enable SVD detection)
6. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

#### Terminating detection

Follow the procedure shown below to stop SVD operation.

1. Write 0x0096 to the MSCPROT.PROT[15:0] bits. (Remove system protection)
2. Write 0 to the SVDCTL.MODEN bit. (Disable SVD detection)
3. Write a value other than 0x0096 to the MSCPROT.PROT[15:0] bits. (Set system protection)

#### Reading detection results

The following two detection results can be obtained by reading the SVDINTF.SVDDT bit:

- Power supply voltage ( $V_{DD}$  or EXSVD)  $\geq$  SVD detection voltage  $V_{SVD}$  when SVDINTF.SVDDT bit = 0
- Power supply voltage ( $V_{DD}$  or EXSVD)  $<$  SVD detection voltage  $V_{SVD}$  when SVDINTF.SVDDT bit = 1

Before reading the SVDINTF.SVDDT bit, wait for at least SVD circuit enable response time after 1 is written to the SVDCTL.MODEN bit (refer to “Supply Voltage Detector Characteristics, SVD circuit enable response time  $t_{SVEN}$ ” in the “Electrical Characteristics” chapter).

After the SVDCTL.SVDC[4:0] bits setting value is altered to change the SVD detection voltage  $V_{SVD}$  when the SVDCTL.MODEN bit = 1, wait for at least SVD circuit response time before reading the SVDINTF.SVDDT bit (refer to “Supply Voltage Detector Characteristics, SVD circuit response time  $t_{SVD}$ ” in the “Electrical Characteristics” chapter).

## 10.4.2 SVD Operations

### Continuous operation mode

SVD operates in continuous operation mode by default (SVDCTL.SVDMMD[1:0] bits = 0x0). In this mode, SVD operates continuously while the SVDCTL.MODEN bit is set to 1 and it keeps loading the detection results to the SVDINTF.SVDDT bit. During this period, the current detection results can be obtained by reading the SVDINTF.SVDDT bit as necessary. Furthermore, an interrupt (if the SVDCTL.SVDRE[3:0] bits ≠ 0xa) or a reset (if the SVDCTL.SVDRE[3:0] bits = 0xa) can be generated when the SVDINTF.SVDDT bit is set to 1 (low power supply voltage is detected). This mode can keep detecting power supply voltage drop after the voltage detection masking time has elapsed even if the IC is placed into SLEEP status or accidental clock stoppage has occurred.

### Intermittent operation mode

SVD operates in intermittent operation mode when the SVDCTL.SVDMMD[1:0] bits are set to 0x1 to 0x3. In this mode, SVD turns on at an interval set using the SVDCTL.SVDMMD[1:0] bits to perform detection operation and then it turns off while the SVDCTL.MODEN bit is set to 1. During this period, the latest detection results can be obtained by reading the SVDINTF.SVDDT bit as necessary. Furthermore, an interrupt or a reset can be generated when SVD has successively detected low power supply voltage the number of times specified by the SVDCTL.SVDSC[1:0] bits.

(1) When the SVDCTL.SVDMMD[1:0] bits = 0x0 (continuous operation mode)

(2) When the SVDCTL.SVDMMD[1:0] bits ≠ 0x0 (intermittent operation mode)

Figure 10.4.2.1 SVD Operations

## 10.5 SVD Interrupt and Reset

### 10.5.1 SVD Interrupt

Setting the SVDCTL.SVDRE[3:0] bits to a value other than 0xa allows use of the low power supply voltage detection interrupt function.

Table 10.5.1.1 Low Power Supply Voltage Detection Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Low power supply voltage detection	SVDINTF.SVDIF	In continuous operation mode When the SVDINTF.SVDDT bit is 1 In intermittent operation mode When low power supply voltage is successively detected the specified number of times	Writing 1

SVD provides the interrupt enable bit (SVDINTE.SVDIE bit) corresponding to the interrupt flag (SVDINTF.SVDIF bit). An interrupt request is sent to the interrupt controller only when the SVDINTF.SVDIF bit is set while the interrupt is enabled by the SVDINTE.SVDIE bit. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

Once the SVDINTF.SVDIF bit is set, it will not be cleared even if the power supply voltage subsequently returns to a value exceeding the SVD detection voltage  $V_{svd}$ . An interrupt may occur due to a temporary power supply voltage drop, check the power supply voltage status by reading the SVDINTF.SVDDT bit in the interrupt handler routine.

## 10.5.2 SVD Reset

Setting the SVDCTL.SVDRE[3:0] bits to 0xa allows use of the SVD reset issuance function.

The reset issuing timing is the same as that of the SVDINTF.SVDIF bit being set when a low voltage is detected.

After a reset has been issued, SVD enters continuous operation mode even if it was operating in intermittent operation mode, and continues operating. Issuing an SVD reset initializes the port assignment. However, when EXSVD is being detected, the input of the port for the EXSVD pin is sent to SVD so that SVD will continue the EXSVD detection operation.

If the power supply voltage reverts to the normal level, the SVDINTF.SVDDT bit goes 0 and the reset state is canceled. After that, SVD resumes operating in the operation mode set previously via the initialization routine.

During reset state, the SVD control bits are set as shown in Table 10.5.2.1.

Table 10.5.2.1 SVD Control Bits During Reset State

Control register	Control bit	Setting
SVDCLK	DBRUN	Reset to the initial values.
	CLKDIV[2:0]	
	CLKSRC[1:0]	
SVDCTL	VDSEL	The set value is retained.
	SVDSC[1:0]	Cleared to 0. (The set value becomes invalid as SVD enters continuous operation mode.)
	SVDC[4:0]	The set value is retained.
	SVDRE[3:0]	The set value (0xa) is retained.
	SVDMD[1:0]	Cleared to 0 to set continuous operation mode.
	MODEN	The set value (1) is retained.
SVDINTF	SVDIF	The status (1) before being reset is retained.
SVDINTE	SVDIE	Cleared to 0.

## 10.6 Control Registers

### SVD Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SVDCLK	15–9	–	0x00	–	R	–
	8	DBRUN	1	H0	R/WP	
	7	–	0	–	R	
	6–4	CLKDIV[2:0]	0x0	H0	R/WP	
	3–2	–	0x0	–	R	
	1–0	CLKSRC[1:0]	0x0	H0	R/WP	

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the SVD operating clock is supplied in DEBUG mode or not.

1 (R/WP): Clock supplied in DEBUG mode

0 (R/WP): No clock supplied in DEBUG mode

**Bit 7 Reserved**

**Bits 6–4 CLKDIV[2:0]**

These bits select the division ratio of the SVD operating clock.

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of SVD.

## 10 SUPPLY VOLTAGE DETECTOR (SVD)

Table 10.6.1 Clock Source and Division Ratio Settings

SVDCLK. CLKDIV[2:0] bits	SVDCLK.CLKSRC[1:0] bits			
	0x0	0x1	0x2	0x3
	IOSC	OSC1	OSC3	EXOSC
0x6, 0x7	Reserved	1/1	Reserved	1/1
0x5	1/128		1/128	
0x4	1/64		1/64	
0x3	1/32		1/32	
0x2	1/16		1/16	
0x1	1/8		1/8	
0x0	1/4		1/4	

(Note) The oscillation circuits/external input that are not supported in this IC cannot be selected as the clock source.

**Note:** The clock frequency should be set to around 32 kHz.

### SVD Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SVDCTL	15	VDSEL	0	H1	R/WP	–
	14–13	SVDSC[1:0]	0x0	H0	R/WP	Writing takes effect when the SVDCTL.SVDMMD[1:0] bits are not 0x0.
	12–8	SVDC[4:0]	0x1e	H1	R/WP	–
	7–4	SVDRE[3:0]	0x0	H1	R/WP	–
	3	–	0	–	R	–
	2–1	SVDMMD[1:0]	0x0	H0	R/WP	–
	0	MODEN	0	H1	R/WP	–

#### Bit 15 VDSEL

This bit selects the power supply voltage to be detected by SVD.

1 (R/WP): Voltage applied to the EXSVD pin

0 (R/WP): V<sub>DD</sub>

#### Bits 14–13 SVDSC[1:0]

These bits set the condition to generate an interrupt/reset (number of successive low voltage detections) in intermittent operation mode (SVDCTL.SVDMMD[1:0] bits = 0x1 to 0x3).

Table 10.6.2 Interrupt/Reset Generating Condition in Intermittent Operation Mode

SVDCTL.SVDSC[1:0] bits	Interrupt/reset generating condition
0x3	Low power supply voltage is successively detected eight times.
0x2	Low power supply voltage is successively detected four times.
0x1	Low power supply voltage is successively detected twice.
0x0	Low power supply voltage is successively detected once.

This setting is ineffective in continuous operation mode (SVDCTL.SVDMMD[1:0] bits = 0x0).

#### Bits 12–8 SVDC[4:0]

These bits select an SVD detection voltage V<sub>svd</sub> for detecting low voltage from among 30 levels.

Table 10.6.3 Setting of SVD Detection Voltage V<sub>svd</sub>

SVDCTL.SVDC[4:0] bits	SVD detection voltage V <sub>svd</sub> [V]
0x1e	High
0x1d	↑
0x1c	
:	
0x02	↓
0x01	Low
0x00, 0x1f	Use prohibited

For more information, refer to “Supply Voltage Detector Characteristics, SVD detection voltage V<sub>svd</sub>” in the “Electrical Characteristics” chapter.

**Bits 7–4 SVDRE[3:0]**

These bits enable/disable the reset issuance function when a low power supply voltage is detected.

0xa (R/WP): Enable (Issue reset)

Other than 0xa (R/WP): Disable (Generate interrupt)

For more information on the SVD reset issuance function, refer to “SVD Reset.”

**Bit 3 Reserved****Bits 2–1 SVDMD[1:0]**

These bits select intermittent operation mode and its detection cycle.

Table 10.6.4 Intermittent Operation Mode Detection Cycle Selection

SVDCTL.SVDMD[1:0] bits	Operation mode (detection cycle)
0x3	Intermittent operation mode (CLK_SVD/512)
0x2	Intermittent operation mode (CLK_SVD/256)
0x1	Intermittent operation mode (CLK_SVD/128)
0x0	Continuous operation mode

For more information on intermittent and continuous operation modes, refer to “SVD Operations.”

**Bit 0 MODEN**

This bit enables/disables for the SVD circuit to operate.

1 (R/WP): Enable (Start detection operations)

0 (R/WP): Disable (Stop detection operations)

After this bit has been altered, wait until the value written is read out from this bit without subsequent operations being performed.

- Notes:**
- Writing 0 to the SVDCTL.MODEN bit resets the SVD hardware. However, the register values set and the interrupt flag are not cleared. The SVDCTL.MODEN bit is actually set to 0 after this processing has finished. If 1 is written to the SVDCTL.MODEN bit continuously without waiting for the bit being read as 0 at this time, writing 0 may be ignored and a malfunction may occur as the hardware restarts without resetting.
  - The SVD internal circuit is initialized if the SVDCTL.SVDSC[1:0] bits, SVDCTL.SVDRE[3:0] bits, or SVDCTL.SVDMD[1:0] bits are altered while SVD is in operation after 1 is written to the SVDCTL.MODEN bit.

**SVD Status and Interrupt Flag Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SVDINTF	15–9	–	0x00	–	R	–
	8	SVDDT	x	–	R	
	7–1	–	0x00	–	R	
	0	SVDIF	0	H1	R/W	Cleared by writing 1.

**Bits 15–9 Reserved****Bit 8 SVDDT**

The power supply voltage detection results can be read out from this bit.

1 (R): Power supply voltage ( $V_{DD}$  or EXSVD) < SVD detection voltage  $V_{SVD}$

0 (R): Power supply voltage ( $V_{DD}$  or EXSVD)  $\geq$  SVD detection voltage  $V_{SVD}$

**Bits 7–1 Reserved****Bit 0 SVDIF**

This bit indicates the low power supply voltage detection interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

## 10 SUPPLY VOLTAGE DETECTOR (SVD)

**Note:** The SVD internal circuit is initialized if the interrupt flag is cleared while SVD is in operation after 1 is written to the SVDCTL.MODEN bit.

### SVD Interrupt Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SVDINTE	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	SVDIE	0	H0	R/W	

**Bits 15–1** Reserved

**Bit 0** SVDIE

This bit enables low power supply voltage detection interrupts.

1 (R/W): Enable interrupts

0 (R/W): Disable interrupts

- Notes:**
- If the SVDCTL.SVDRE[3:0] bits are set to 0xa, no low power supply voltage detection interrupt will occur, as a reset is issued at the same timing as an interrupt.
  - To prevent generating unnecessary interrupts, the corresponding interrupt flag should be cleared before enabling interrupts.

# 11 16-bit Timers (T16)

## 11.1 Overview

T16 is a 16-bit timer. The features of T16 are listed below.

- 16-bit presettable down counter
- Provides a reload data register for setting the preset value.
- A clock source and clock division ratio for generating the count clock are selectable.
- Repeat mode or one-shot mode is selectable.
- Can generate counter underflow interrupts.

Figure 11.1.1 shows the configuration of a T16 channel.

Table 11.1.1 T16 Channel Configuration of S1C17W03/W04

Item	32-pin package	48-pin package/chip
Number of channels	4 channels (Ch.0–Ch.3)	
Event counter function	Not supported (No EXCL <sub>m</sub> pins are provided.)	
Peripheral clock output (Outputs the counter underflow signal.)	Ch.1 → Synchronous serial interface Ch.0 master clock Ch.2 → Synchronous serial interface Ch.1 master clock Ch.3 → 12-bit A/D converter trigger signal	

Figure 11.1.1 Configuration of a T16 Channel

## 11.2 Input Pin

Table 11.2.1 shows the T16 input pin.

Table 11.2.1 T16 Input Pin

Pin name	I/O*	Initial status*	Function
EXCL <sub>m</sub>	I	I (Hi-Z)	External event signal input pin

\* Indicates the status when the pin is configured for T16.

If the port is shared with the EXCL<sub>m</sub> pin and other functions, the EXCL<sub>m</sub> input function must be assigned to the port before using the event counter function. For more information, refer to the “I/O Ports” chapter.

## 11.3 Clock Settings

### 11.3.1 T16 Operating Clock

When using T16 Ch.*n*, the T16 Ch.*n* operating clock CLK\_T16\_*n* must be supplied to T16 Ch.*n* from the clock generator. The CLK\_T16\_*n* supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following T16\_*n*CLK register bits:
  - T16\_*n*CLK.CLKSRC[1:0] bits (Clock source selection)
  - T16\_*n*CLK.CLKDIV[3:0] bits (Clock division ratio selection = Clock frequency setting)

### 11.3.2 Clock Supply in SLEEP Mode

When using T16 during SLEEP mode, the T16 operating clock CLK\_T16\_*n* must be configured so that it will keep supplying by writing 0 to the CLGOSC.*xxx*SLPC bit for the CLK\_T16\_*n* clock source.

If the CLGOSC.*xxx*SLPC bit for the CLK\_T16\_*n* clock source is 1, the CLK\_T16\_*n* clock source is deactivated during SLEEP mode and T16 stops with the register settings and counter value maintained at those before entering SLEEP mode. After the CPU returns to normal mode, CLK\_T16\_*n* is supplied and the T16 operation resumes.

### 11.3.3 Clock Supply in DEBUG Mode

The CLK\_T16\_*n* supply during DEBUG mode should be controlled using the T16\_*n*CLK.DBRUN bit.

The CLK\_T16\_*n* supply to T16 Ch.*n* is suspended when the CPU enters DEBUG mode if the T16\_*n*CLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_T16\_*n* supply resumes. Although T16 Ch.*n* stops operating when the CLK\_T16\_*n* supply is suspended, the counter and registers retain the status before DEBUG mode was entered. If the T16\_*n*CLK.DBRUN bit = 1, the CLK\_T16\_*n* supply is not suspended and T16 Ch.*n* will keep operating in DEBUG mode.

### 11.3.4 Event Counter Clock

The channel that supports the event counter function counts down at the rising edge of the EXCL<sub>*m*</sub> pin input signal when the T16\_*n*CLK.CLKSRC[1:0] bits are set to 0x3.

Figure 11.3.4.1 Count Down Timing

Note that the EXOSC clock is selected for the channel that does not support the event counter function.

## 11.4 Operations

### 11.4.1 Initialization

T16 Ch.*n* should be initialized and started counting with the procedure shown below.

1. Configure the T16 Ch.*n* operating clock (see “T16 Operating Clock”).
2. Set the T16\_*n*CTL.MODEN bit to 1. (Enable count operation clock)
3. Set the T16\_*n*MOD.TRMD bit. (Select operation mode (Repeat mode or One-shot mode)).
4. Set the T16\_*n*TR register. (Set reload data (counter preset data))
5. Set the following bits when using the interrupt:
  - Write 1 to the T16\_*n*INTF.UFIF bit. (Clear interrupt flag)
  - Set the T16\_*n*INTE.UFIE bit to 1. (Enable underflow interrupt)

6. Set the following T16\_nCTL register bits:
  - Set the T16\_nCTL.PRESET bit to 1. (Preset reload data to counter)
  - Set the T16\_nCTL.PRUN bit to 1. (Start counting)

### 11.4.2 Counter Underflow

Normally, the T16 counter starts counting down from the reload data value preset and generates an underflow signal when an underflow occurs. This signal is used to generate an interrupt and may be output to a specific peripheral circuit as a clock (T16 Ch.n must be set to repeat mode to generate a clock). The underflow cycle is determined by the T16 Ch.n operating clock setting and reload data (counter initial value) set in the T16\_nTR register.

The following shows the equations to calculate the underflow cycle and frequency:

$$T = \frac{TR + 1}{f_{CLK\_T16\_n}} \quad f_T = \frac{f_{CLK\_T16\_n}}{TR + 1} \quad (\text{Eq. 11.1})$$

Where

- T: Underflow cycle [s]
- f<sub>T</sub>: Underflow frequency [Hz]
- TR: T16\_nTR register setting
- f<sub>CLK\_T16\_n</sub>: T16 Ch.n operating clock frequency [Hz]

### 11.4.3 Operations in Repeat Mode

T16 Ch.n enters repeat mode by setting the T16\_nMOD.TRMD bit to 0.

In repeat mode, the count operation starts by writing 1 to the T16\_nCTL.PRUN bit and continues until 0 is written. A counter underflow presets the T16\_nTR register value to the counter, so underflow occurs periodically. Select this mode to generate periodic underflow interrupts or when using the timer to output a trigger/clock to the peripheral circuit.

Figure 11.4.3.1 Count Operations in Repeat Mode

### 11.4.4 Operations in One-shot Mode

T16 Ch.n enters one-shot mode by setting the T16\_nMOD.TRMD bit to 1.

In one-shot mode, the count operation starts by writing 1 to the T16\_nCTL.PRUN bit and stops after the T16\_nTR register value is preset to the counter when an underflow has occurred. At the same time the counter stops, the T16\_nCTL.PRUN bit is cleared automatically. Select this mode to stop the counter after an interrupt has occurred once, such as for checking a specific lapse of time.

## 11 16-BIT TIMERS (T16)

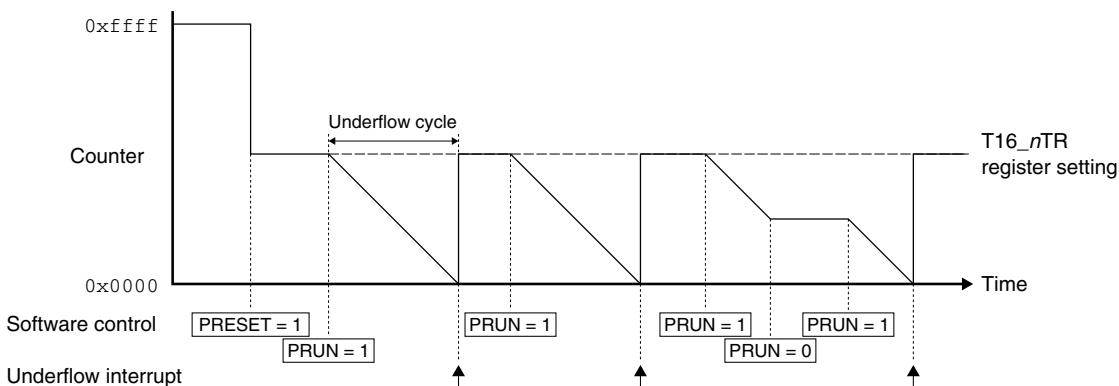

Figure 11.4.4.1 Count Operations in One-shot Mode

### 11.4.5 Counter Value Read

The counter value can be read out from the T16\_nTC.TC[15:0] bits. However, since T16 operates on CLK\_T16\_n, one of the operations shown below is required to read correctly by the CPU.

- Read the counter value twice or more and check to see if the same value is read.
- Stop the timer and then read the counter value.

## 11.5 Interrupt

Each T16 channel has a function to generate the interrupt shown in Table 11.5.1.

Table 11.5.1 T16 Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Underflow	T16_nINTF.UFIF	When the counter underflows	Writing 1

T16 provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 11.6 Control Registers

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the T16 Ch.n operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

**Bits 7–4 CLKDIV[3:0]**

These bits select the division ratio of the T16 Ch.n operating clock (counter clock).

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of T16 Ch.n.

(Note 2) When the T16\_nCLK.CLKSRC[1:0] bits are set to 0x3, EXCLm is selected for the channel with an event counter function or EXOSC is selected for other channels.

## T16 Ch.n Mode Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_nMOD	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	TRMD	0	H0	R/W	

### Bits 15–1 Reserved

#### Bit 0 TRMD

This bit selects the T16 operation mode.

1 (R/W): One-shot mode

0 (R/W): Repeat mode

For detailed information on the operation mode, refer to “Operations in One-shot Mode” and “Operations in Repeat Mode.”

## T16 Ch.n Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_nCTL	15–9	–	0x00	–	R	–
	8	PRUN	0	H0	R/W	
	7–2	–	0x00	–	R	
	1	PRESET	0	H0	R/W	
	0	MODEN	0	H0	R/W	

### Bits 15–9 Reserved

#### Bit 8 PRUN

This bit starts/stops the timer.

1 (W): Start timer

0 (W): Stop timer

1 (R): Timer is running

0 (R): Timer is idle

## 11 16-BIT TIMERS (T16)

By writing 1 to this bit, the timer starts count operations. However, the T16\_nCTL.MODEN bit must be set to 1 in conjunction with this bit or it must be set in advance. While the timer is running, writing 0 to this bit stops count operations. When the counter stops due to a counter underflow in one-shot mode, this bit is automatically cleared to 0.

### Bits 7–2 Reserved

#### Bit 1 PRESET

This bit presets the reload data stored in the T16\_nTR register to the counter.

- 1 (W): Preset
- 0 (W): Ineffective
- 1 (R): Presetting in progress
- 0 (R): Presetting finished or normal operation

By writing 1 to this bit, the timer presets the T16\_nTR register value to the counter. However, the T16\_nCTL.MODEN bit must be set to 1 in conjunction with this bit or it must be set in advance. This bit retains 1 during presetting and is automatically cleared to 0 after presetting has finished.

#### Bit 0 MODEN

This bit enables the T16 Ch.n operations.

- 1 (R/W): Enable (Start supplying operating clock)
- 0 (R/W): Disable (Stop supplying operating clock)

## T16 Ch.n Reload Data Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_nTR	15–0	TR[15:0]	0xffff	H0	R/W	–

### Bits 15–0 TR[15:0]

These bits are used to set the initial value to be preset to the counter.

The value set to this register will be preset to the counter when 1 is written to the T16\_nCTL.PRESET bit or when the counter underflows.

- Notes:**
- The T16\_nTR register cannot be altered while the timer is running (T16\_nCTL.PRUN bit = 1), as an incorrect initial value may be preset to the counter.
  - When one-shot mode is set, the T16\_nTR.TR[15:0] bits should be set to a value equal to or greater than 0x0001.

## T16 Ch.n Counter Data Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_nTC	15–0	TC[15:0]	0xffff	H0	R	–

### Bits 15–0 TC[15:0]

The current counter value can be read out from these bits.

## T16 Ch.n Interrupt Flag Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_nINTF	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	UFIF	0	H0	R/W	Cleared by writing 1.

### Bits 15–1 Reserved

#### Bit 0 UFIF

This bit indicates the T16 Ch.n underflow interrupt cause occurrence status.

- 1 (R): Cause of interrupt occurred
- 0 (R): No cause of interrupt occurred
- 1 (W): Clear flag
- 0 (W): Ineffective

## T16 Ch.*n* Interrupt Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16_ <i>n</i> INTE	15-8	-	0x00	-	R	-
	7-1	-	0x00	-	R	
	0	UFIE	0	H0	R/W	

**Bits 15-1** Reserved

**Bit 0** **UFIE**

This bit enables T16 Ch.*n* underflow interrupts.

1 (R/W): Enable interrupts

0 (R/W): Disable interrupts

**Note:** To prevent generating unnecessary interrupts, the corresponding interrupt flag should be cleared before enabling interrupts.

# 12 UART (UART)

## 12.1 Overview

The UART is an asynchronous serial interface. The features of the UART are listed below.

- Includes a baud rate generator for generating the transfer clock.
- Supports 7- and 8-bit data length (LSB first).
- Odd parity, even parity, or non-parity mode is selectable.
- The start bit length is fixed at 1 bit.
- The stop bit length is selectable from 1 bit and 2 bits.
- Supports full-duplex communications.
- Includes a 2-byte receive data buffer and a 1-byte transmit data buffer.
- Includes an RZI modulator/demodulator circuit to support IrDA 1.0-compatible infrared communications.
- Can detect parity error, framing error, and overrun error.
- Can generate receive buffer full (1 byte/2 bytes), transmit buffer empty, end of transmission, parity error, framing error, and overrun error interrupts.
- Input pin can be pulled up with an internal resistor.
- The output pin is configurable as an open-drain output.

Figure 12.1.1 shows the UART configuration.

## 12.2 Input/Output Pins and External Connections

### 12.2.1 List of Input/Output Pins

Table 12.2.1.1 lists the UART pins.

Table 12.2.1.1 List of UART Pins

Pin name	I/O*	Initial status*	Function
USIN $n$	I	I (Hi-Z)	UART Ch. $n$ data input pin
USOUT $n$	O	O (High)	UART Ch. $n$ data output pin

\* Indicates the status when the pin is configured for the UART.

If the port is shared with the UART pin and other functions, the UART input/output function must be assigned to the port before activating the UART. For more information, refer to the “I/O Ports” chapter.

### 12.2.2 External Connections

Figure 12.2.2.1 shows a connection diagram between the UART in this IC and an external UART device.

Figure 12.2.2.1 Connections between UART and an External UART Device

### 12.2.3 Input Pin Pull-Up Function

The UART includes a pull-up resistor for the USIN $n$  pin. Setting the UAnMOD.PUEN bit to 1 enables the resistor to pull up the USIN $n$  pin.

### 12.2.4 Output Pin Open-Drain Output Function

The USOUT $n$  pin supports the open-drain output function. Default configuration is a push-pull output and it is switched to an open-drain output by setting the UAnMOD.OUTMD bit to 1.

## 12.3 Clock Settings

### 12.3.1 UART Operating Clock

When using the UART Ch. $n$ , the UART Ch. $n$  operating clock CLK\_UART $n$  must be supplied to the UART Ch. $n$  from the clock generator. The CLK\_UART $n$  supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following UAnCLK register bits:
  - UAnCLK.CLKSRC[1:0] bits (Clock source selection)
  - UAnCLK.CLKDIV[1:0] bits (Clock division ratio selection = Clock frequency setting)

The UART operating clock should be selected so that the baud rate generator will be configured easily.

### 12.3.2 Clock Supply in SLEEP Mode

When using the UART during SLEEP mode, the UART operating clock CLK\_UART $n$  must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_UART $n$  clock source.

### 12.3.3 Clock Supply in DEBUG Mode

The CLK\_UART $n$  supply during DEBUG mode should be controlled using the UA $n$ CLK.DBRUN bit.

The CLK\_UART $n$  supply to the UART Ch. $n$  is suspended when the CPU enters DEBUG mode if the UA $n$ CLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_UART $n$  supply resumes. Although the UART Ch. $n$  stops operating when the CLK\_UART $n$  supply is suspended, the output pin and registers retain the status before DEBUG mode was entered. If the UA $n$ CLK.DBRUN bit = 1, the CLK\_UART $n$  supply is not suspended and the UART Ch. $n$  will keep operating in DEBUG mode.

### 12.3.4 Baud Rate Generator

The UART includes a baud rate generator to generate the transfer (sampling) clock. The transfer rate is determined by the UA $n$ BR.BRT[7:0] and UA $n$ BR.FMD[3:0] bit settings. Use the following equations to calculate the setting values for obtaining the desired transfer rate.

$$\text{bps} = \frac{\text{CLK\_UART}}{\{(BRT + 1) \times 16 + FMD\}} \quad \text{BRT} = \left( \frac{\text{CLK\_UART}}{\text{bps}} - FMD - 16 \right) \div 16 \quad (\text{Eq. 12.1})$$

Where

- CLK\_UART: UART operating clock frequency [Hz]
- bps: Transfer rate [bit/s]
- BRT: UA $n$ BR.BRT[7:0] setting value (0 to 255)
- FMD: UA $n$ BR.FMD[3:0] setting value (0 to 15)

For the transfer rate range configurable in the UART, refer to “UART Characteristics, Transfer baud rates U $BRT_1$  and U $BRT_2$ ” in the “Electrical Characteristics” chapter.

## 12.4 Data Format

The UART allows setting of the data length, stop bit length, and parity function. The start bit length is fixed at one bit.

### Data length

With the UA $n$ MOD.CHLN bit, the data length can be set to seven bits (UA $n$ MOD.CHLN bit = 0) or eight bits (UA $n$ MOD.CHLN bit = 1).

### Stop bit length

With the UA $n$ MOD.STPB bit, the stop bit length can be set to one bit (UA $n$ MOD.STPB bit = 0) or two bits (UA $n$ MOD.STPB bit = 1).

### Parity function

The parity function is configured using the UA $n$ MOD.PREN and UA $n$ MOD.PRMD bits.

Table 12.4.1 Parity Function Setting

UA $n$ MOD.PREN bit	UA $n$ MOD.PRMD bit	Parity function
1	1	Odd parity
1	0	Even parity
0	*	Non parity

## 12 UART (UART)

## 12.5 Operations

### 12.5.1 Initialization

The UART Ch.*n* should be initialized with the procedure shown below.

1. Assign the UART Ch.*n* input/output function to the ports. (Refer to the “I/O Ports” chapter.)
2. Set the UAnCLK.CLKSRC[1:0] and UAnCLK.CLKDIV[1:0] bits. (Configure operating clock)
3. Configure the following UAnMOD register bits:
  - UAnMOD.PUEN bit (Enable/disable USIN*n* pin pull-up)
  - UAnMOD.OUTMD bit (Enable/disable USOUT*n* pin open-drain output)
  - UAnMOD.IRMD bit (Enable/disable IrDA interface)
  - UAnMOD.CHLN bit (Set 7/8-bit data length)
  - UAnMOD.PREN bit (Enable/disable parity function)
  - UAnMOD.PRMD bit (Even/odd parity selection)
  - UAnMOD.STPB bit (Set 1/2-bit stop bit length)
4. Set the UAnBR.BRT[7:0] and UAnBR.FMD[3:0] bits. (Set transfer rate)
5. Set the following UAnCTL register bits:
  - Set the UAnCTL.SFTRST bit to 1. (Execute software reset)
  - Set the UAnCTL.MODEN bit to 1. (Enable UART Ch.*n* operations)
6. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the UAnINTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the UAnINTE register to 1. \* (Enable interrupts)

\* The initial value of the UAnINTF.TBEIF bit is 1, therefore, an interrupt will occur immediately after the UAnINTE.TBEIE bit is set to 1.

### 12.5.2 Data Transmission

A data sending procedure and the UART Ch.*n* operations are shown below. Figures 12.5.2.1 and 12.5.2.2 show a timing chart and a flowchart, respectively.

#### Data sending procedure

1. Check to see if the UAnINTF.TBEIF bit is set to 1 (transmit buffer empty).
2. Write transmit data to the UAnTXD register.
3. Wait for a UART interrupt when using the interrupt.
4. Repeat Steps 1 to 3 (or 1 and 2) until the end of transmit data.

## UART data sending operations

The UART Ch.*n* starts data sending operations when transmit data is written to the UAnTXD register.

The transmit data in the UAnTXD register is automatically transferred to the shift register and the UAnINTF.TBEIF bit is set to 1 (transmit buffer empty).

The USOUT<sub>*n*</sub> pin outputs a start bit and the UAnINTF.TBSY bit is set to 1 (transmit busy). The shift register data bits are then output successively from the LSB. Following output of MSB, the parity bit (if parity is enabled) and the stop bit are output.

Even if transmit data is being output from the USOUT<sub>*n*</sub> pin, the next transmit data can be written to the UAnTXD register after making sure the UAnINTF.TBEIF bit is set to 1.

If no transmit data remains in the UAnTXD register after the stop bit has been output from the USOUT<sub>*n*</sub> pin, the UAnINTF.TBSY bit is cleared to 0 and the UAnINTF.TENDIF bit is set to 1 (transmission completed).

Figure 12.5.2.1 Example of Data Sending Operations

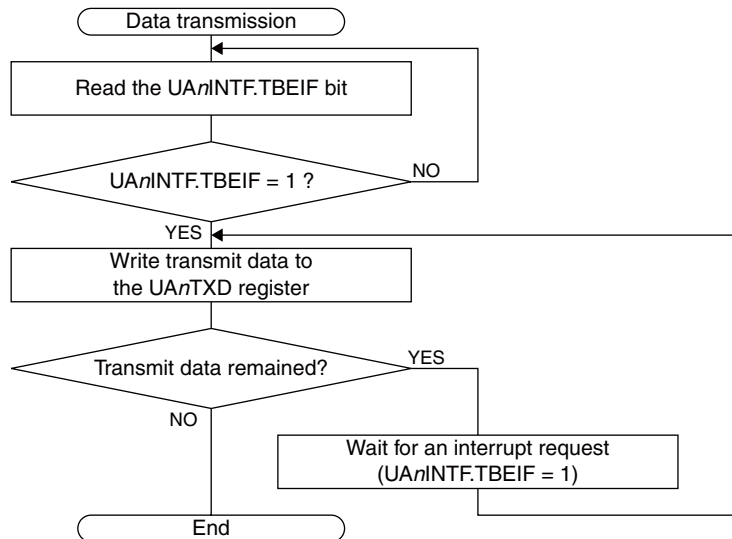

Figure 12.5.2.2 Data Transmission Flowchart

## 12.5.3 Data Reception

A data receiving procedure and the UART Ch.*n* operations are shown below. Figures 12.5.3.1 and 12.5.3.2 show a timing chart and flowcharts, respectively.

### Data receiving procedure (read by one byte)

1. Wait for a UART interrupt when using the interrupt.
2. Check to see if the UAnINTF.RB1FIF bit is set to 1 (receive buffer one byte full).
3. Read the received data from the UAnRXD register.
4. Repeat Steps 1 to 3 (or 2 and 3) until the end of data reception.

### Data receiving procedure (read by two bytes)

1. Wait for a UART interrupt when using the interrupt.
2. Check to see if the  $UA_nINTF.RB2FIF$  bit is set to 1 (receive buffer two bytes full).
3. Read the received data from the  $UA_nRXD$  register twice.
4. Repeat Steps 1 to 3 (or 2 and 3) until the end of data reception.

### UART data receiving operations

The UART Ch. $n$  starts data receiving operations when a start bit is input to the  $USIN_n$  pin.

After the receive circuit has detected a low level as a start bit, it starts sampling the following data bits and loads the received data into the receive shift register. The  $UA_nINTF.RBSY$  bit is set to 1 when the start bit is detected.

The  $UA_nINTF.RBSY$  bit is cleared to 0 and the receive shift register data is transferred to the receive data buffer at the stop bit receive timing.

The receive data buffer consists of a 2-byte FIFO and receives data until it becomes full. When the receive data buffer receives the first data, it sets the  $UA_nINTF.RB1FIF$  bit to 1 (receive buffer one byte full). If the second data is received without reading the first data, the  $UA_nINTF.RB2FIF$  bit is set to 1 (receive buffer two bytes full).

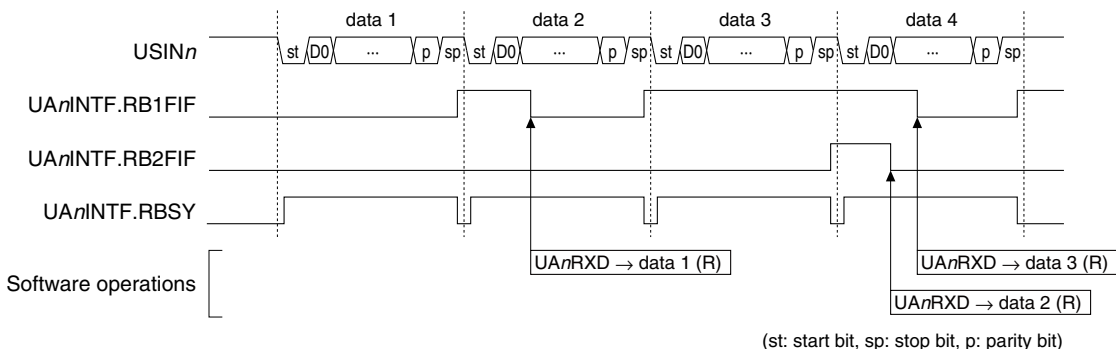

Figure 12.5.3.1 Example of Data Receiving Operations

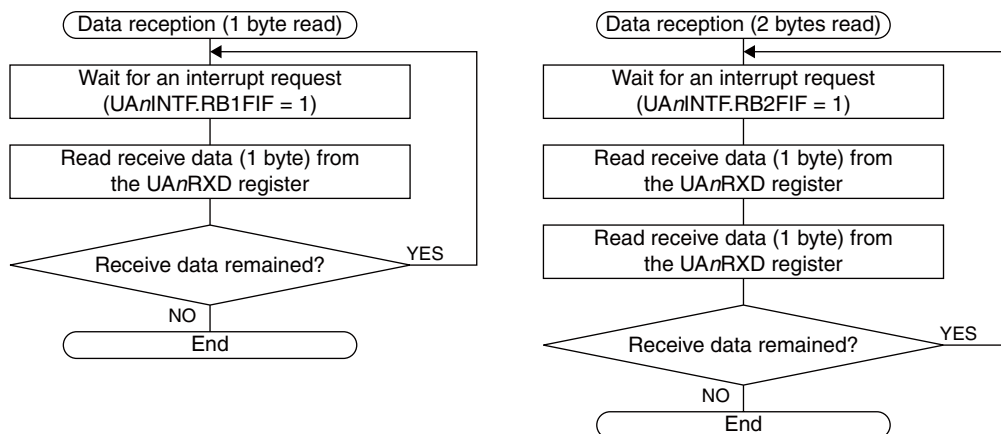

Figure 12.5.3.2 Data Reception Flowcharts

## 12.5.4 IrDA Interface

This UART includes an RZI modulator/demodulator circuit enabling implementation of IrDA 1.0-compatible infrared communication function simply by adding simple external circuits.

Set the  $UA_nMOD.IRMD$  bit to 1 to use the IrDA interface.

Data transfer control is identical to that for normal interface even if the IrDA interface function is enabled.

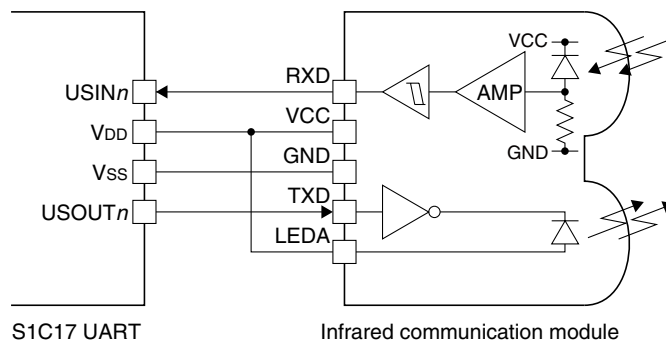

Figure 12.5.4.1 Example of Connections with an Infrared Communication Module

The transmit data output from the UART Ch. $n$  transmit shift register is output from the USOUT $n$  pin after the low pulse width is converted into  $3/16$  by the RZI modulator in SIR method and inverted. The USOUT $n$  pin output signal can be inverted by setting the UA $n$ MOD.INVIRTX bit to 1.

Figure 12.5.4.2 IrDA Transmission Signal Waveform

The received IrDA signal is input to the RZI demodulator and the low pulse width is converted into the normal width before input to the receive shift register. The USIN $n$  pin input signal can be inverted prior to being demodulated by setting the UA $n$ MOD.INVIRRX bit to 1.

Figure 12.5.4.3 IrDA Receive Signal Waveform

**Note:** The low pulse width ( $T_2$ ) of the IrDA signal input must be  $\text{CLK\_UART} \times 3$  cycles or longer.

## 12.6 Receive Errors

Three different receive errors, framing error, parity error, and overrun error, may be detected while receiving data. Since receive errors are interrupt causes, they can be processed by generating interrupts.

### 12.6.1 Framing Error

The UART determines loss of sync if a stop bit is not detected (when the stop bit is received as 0) and assumes that a framing error has occurred. The received data that encountered an error is still transferred to the receive data buffer and the UA $n$ INTF.FEIF bit (framing error interrupt flag) is set to 1 when the data becomes ready to read from the UA $n$ RXD register.

**Note:** Framing error/parity error interrupt flag set timings

These interrupt flags will be set after the data that encountered an error is transferred to the receive data buffer. Note, however, that the set timing depends on the buffer status at that point.

- When the receive data buffer is empty

The interrupt flag will be set when the data that encountered an error is transferred to the receive data buffer.

## 12 UART (UART)

- When the receive data buffer has a one-byte free space  
The interrupt flag will be set when the first data byte already loaded is read out after the data that encountered an error is transferred to the second byte entry of the receive data buffer.

### 12.6.2 Parity Error

If the parity function is enabled, a parity check is performed when data is received. The UART checks matching between the data received in the shift register and its parity bit, and issues a parity error if the result is a non-match. The received data that encountered an error is still transferred to the receive data buffer and the  $UA_nINTF.PEIF$  bit (parity error interrupt flag) is set to 1 when the data becomes ready to read from the  $UA_nRXD$  register (see the Note on framing error).

### 12.6.3 Overrun Error

If the receive data buffer is still full (two bytes of received data have not been read) when a data reception to the shift register has completed, an overrun error occurs as the data cannot be transferred to the receive data buffer. When an overrun error occurs, the  $UA_nINTF.OEIF$  bit (overrun error interrupt flag) is set to 1.

## 12.7 Interrupts

The UART has a function to generate the interrupts shown in Table 12.7.1.

Table 12.7.1 UART Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
End of transmission	$UA_nINTF.TENDIF$	When the $UA_nINTF.TBEIF$ bit = 1 after the stop bit has been sent	Writing 1 or software reset
Framing error	$UA_nINTF.FEIF$	Refer to the "Receive Errors."	Writing 1, reading received data that encountered an error, or software reset
Parity error	$UA_nINTF.PEIF$	Refer to the "Receive Errors."	Writing 1, reading received data that encountered an error, or software reset
Overrun error	$UA_nINTF.OEIF$	Refer to the "Receive Errors."	Writing 1 or software reset
Receive buffer two bytes full	$UA_nINTF.RB2FIF$	When the second received data byte is loaded to the receive data buffer in which the first byte is already received	Reading received data or software reset
Receive buffer one byte full	$UA_nINTF.RB1FIF$	When the first received data byte is loaded to the emptied receive data buffer	Reading data to empty the receive data buffer or software reset
Transmit buffer empty	$UA_nINTF.TBEIF$	When transmit data written to the transmit data buffer is transferred to the shift register	Writing transmit data

The UART provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the "Interrupt Controller" chapter.

## 12.8 Control Registers

### UART Ch.n Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
$UA_nCLK$	15-9	-	0x00	-	R	-

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the UART operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

**Bits 7–6 Reserved**

**Bits 5–4 CLKDIV[1:0]**

These bits select the division ratio of the UART operating clock.

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of the UART.

Table 12.8.1 Clock Source and Division Ratio Settings

	1	PRMD	0	H0	R/W	
0	STPB	0	H0	R/W		

**Bits 15–10 Reserved**

**Bit 9 INVIRRX**

This bit enables the USIN $n$  input inverting function when the IrDA interface function is enabled.

1 (R/W): Enable input inverting function

0 (R/W): Disable input inverting function

**Bit 8 INVIRTX**

This bit enables the USOUT $n$  output inverting function when the IrDA interface function is enabled.

1 (R/W): Enable output inverting function

0 (R/W): Disable output inverting function

**Bit 7 Reserved**

**Bit 6 PUEN**

This bit enables pull-up of the USIN $n$  pin.

1 (R/W): Enable pull-up

0 (R/W): Disable pull-up

## 12 UART (UART)

### Bit 5 OUTMD

This bit sets the USOUT $n$  pin output mode.

1 (R/W): Open-drain output

0 (R/W): Push-pull output

### Bit 4 IRMD

This bit enables the IrDA interface function.

1 (R/W): Enable IrDA interface function

0 (R/W): Disable IrDA interface function

### Bit 3 CHLN

This bit sets the data length.

1 (R/W): 8 bits

0 (R/W): 7 bits

### Bit 2 PREN

This bit enables the parity function.

1 (R/W): Enable parity function

0 (R/W): Disable parity function

### Bit 1 PRMD

This bit selects either odd parity or even parity when using the parity function.

1 (R/W): Odd parity

0 (R/W): Even parity

### Bit 0 STPB

This bit sets the stop bit length.

1 (R/W): 2 bits

0 (R/W): 1 bit

**Note:** The UAnMOD register settings can be altered only when the UAnCTL.MODEN bit = 0.

## UART Ch. $n$ Baud–Rate Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
UAnBR	15–12	–	0x0	–	R	–
	11–8	FMD[3:0]	0x0	H0	R/W	
	7–0	BRT[7:0]	0x00	H0	R/W	

### Bits 15–12 Reserved

### Bits 11–8 FMD[3:0]

### Bits 7–0 BRT[7:0]

These bits set the UART transfer rate. For more information, refer to “Baud Rate Generator.”

**Note:** The UAnBR register settings can be altered only when the UAnCTL.MODEN bit = 0.

## UART Ch. $n$ Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
UAnCTL	15–8	–	0x00	–	R	–
	7–2	–	0x00	–	R	
	1	SFTRST	0	H0	R/W	
	0	MODEN	0	H0	R/W	

### Bits 15–2 Reserved

**Bit 1 SFTRST**

This bit issues software reset to the UART.

1 (W): Issue software reset

0 (W): Ineffective

1 (R): Software reset is executing.

0 (R): Software reset has finished. (During normal operation)

Setting this bit resets the UART transmit/receive control circuit and interrupt flags. This bit is automatically cleared after the reset processing has finished.

**Bit 0 MODEN**

This bit enables the UART operations.

1 (R/W): Enable UART operations (The operating clock is supplied.)

0 (R/W): Disable UART operations (The operating clock is stopped.)

**Note:** If the  $UA_nCTL.MODEN$  bit is altered from 1 to 0 while sending/receiving data, the data being sent/received cannot be guaranteed. When setting the  $UA_nCTL.MODEN$  bit to 1 again after that, be sure to write 1 to the  $UA_nCTL.SFTRST$  bit as well.

**UART Ch.n Transmit Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
UA <sub>n</sub> TXD	15–8	–	0x00	–	R	–
	7–0	TXD[7:0]	0x00	H0	R/W	

**Bits 15–8 Reserved**

**Bits 7–0 TXD[7:0]**

Data can be written to the transmit data buffer through these bits. Make sure the  $UA_nINTF.TBEIF$  bit is set to 1 before writing data.

**UART Ch.n Receive Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
UA <sub>n</sub> RXD	15–8	–	0x00	–	R	–
	7–0	RXD[7:0]	0x00	H0	R	

**Bits 15–8 Reserved**

**Bits 7–0 RXD[7:0]**

The receive data buffer can be read through these bits. The receive data buffer consists of a 2-byte FIFO, and older received data is read first.

## 12 UART (UART)

### Bit 9 RBSY

This bit indicates the receiving status. (See Figure 12.5.3.1.)

1 (R): During receiving

0 (R): Idle

### Bit 8 TBSY

This bit indicates the sending status. (See Figure 12.5.2.1.)

1 (R): During sending

0 (R): Idle

### Bit 7 Reserved

### Bit 6 TENDIF

### Bit 5 FEIF

### Bit 4 PEIF

### Bit 3 OEIF

### Bit 2 RB2FIF

### Bit 1 RB1FIF

### Bit 0 TBEIF

These bits indicate the UART interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

The following shows the correspondence between the bit and interrupt:

UAnINTF.TENDIF bit: End-of-transmission interrupt

# 13 Synchronous Serial Interface (SPIA)

## 13.1 Overview

SPIA is a synchronous serial interface. The features of SPIA are listed below.

- Supports both master and slave modes.
- Data length: 2 to 16 bits programmable
- Either MSB first or LSB first can be selected for the data format.
- Clock phase and polarity are configurable.
- Supports full-duplex communications.
- Includes separated transmit data buffer and receive data buffer registers.
- Can generate receive buffer full, transmit buffer empty, end of transmission, and overrun interrupts.
- Master mode allows use of a 16-bit timer to set baud rate.
- Slave mode is capable of being operated with the external input clock  $SPICLK_n$  only.
- Slave mode is capable of being operated in SLEEP mode allowing wake-up by an SPIA interrupt.
- Input pins can be pulled up/down with an internal resistor.

Figure 13.1.1 shows the SPIA configuration.

## 13.2 Input/Output Pins and External Connections

### 13.2.1 List of Input/Output Pins

Table 13.2.1.1 lists the SPIA pins.

Table 13.2.1.1 List of SPIA Pins

Pin name	I/O*	Initial status*	Function
SDIn	I	I (Hi-Z)	SPIA Ch.n data input pin
SDOn	O or Hi-Z	Hi-Z	SPIA Ch.n data output pin
SPICLK <sub>n</sub>	I or O	I (Hi-Z)	SPIA Ch.n external clock input/output pin
#SPISS <sub>n</sub>	I	I (Hi-Z)	SPIA Ch.n slave select signal input pin

\* Indicates the status when the pin is configured for SPIA.

If the port is shared with the SPIA pin and other functions, the SPIA input/output function must be assigned to the port before activating SPIA. For more information, refer to the “I/O Ports” chapter.

### 13.2.2 External Connections

SPIA operates in master mode or slave mode. Figures 13.2.2.1 and 13.2.2.2 show connection diagrams between SPIA in each mode and external SPI devices.

Figure 13.2.2.1 Connections between SPIA in Master Mode and External SPI Slave Devices

Figure 13.2.2.2 Connections between SPIA in Slave Mode and External SPI Master Device

### 13.2.3 Pin Functions in Master Mode and Slave Mode

The pin functions are changed according to the master or slave mode selection. The differences in pin functions between the modes are shown in Table 13.2.3.1.

Table 13.2.3.1 Pin Function Differences between Modes

Pin	Function in master mode	Function in slave mode
<i>SDIn</i>	Always placed into input state.	
<i>SDOn</i>	Always placed into output state.	This pin is placed into output state while a low level is applied to the #SPISS <i>n</i> pin or placed into Hi-Z state while a high level is applied to the #SPISS <i>n</i> pin.
<i>SPICLK<i>n</i></i>	Outputs the SPI clock to external devices. Output clock polarity and phase can be configured if necessary.	Inputs an external SPI clock. Clock polarity and phase can be designated according to the input clock.
#SPISS <i>n</i>	Not used. This input function is not required to be assigned to the port. To output the slave select signal in master mode, use a general-purpose I/O port function.	Applying a low level to the #SPISS <i>n</i> pin enables SPIA to transmit/receive data. While a high level is applied to this pin, SPIA is not selected as a slave device. Data input to the <i>SDIn</i> pin and the clock input to the <i>SPICLK<i>n</i></i> pin are ignored. When a high level is applied, the transmit/receive bit count is cleared to 0 and the already received bits are discarded.

### 13.2.4 Input Pin Pull-Up/Pull-Down Function

The SPIA input pins (*SDIn* in master mode or *SDIn*, *SPICLK*n**, and #SPISS*n* pins in slave mode) have a pull-up or pull-down function as shown in Table 13.2.4.1. This function is enabled by setting the *SPI*n*MOD.PUEN* bit to 1.

Table 13.2.4.1 Pull-Up or Pull-Down of Input Pins

Pin	Master mode	Slave mode
<i>SDIn</i>	Pull-up	Pull-up
<i>SPICLK<i>n</i></i>	–	<i>SPI<i>n</i>MOD.CPOL</i> bit = 1: Pull-up <i>SPI<i>n</i>MOD.CPOL</i> bit = 0: Pull-down
#SPISS <i>n</i>	–	Pull-up

## 13.3 Clock Settings

### 13.3.1 SPIA Operating Clock

#### Operating clock in master mode

In master mode, the SPIA operating clock is supplied from the 16-bit timer. The following two options are provided for the clock configuration.

##### Use the 16-bit timer operating clock without dividing

By setting the *SPI*n*MOD.NOCLKDIV* bit to 1, the operating clock *CLK\_T16\_m*, which is configured by selecting a clock source and a division ratio, for the 16-bit timer channel corresponding to the SPIA channel is input to SPIA as *CLK\_SPIA*n**. Since this clock is also used as the SPI clock *SPICLK*n** without changing, the *CLK\_SPIA*n** frequency becomes the baud rate.

To supply *CLK\_SPIA*n** to SPIA, the 16-bit timer clock source must be enabled in the clock generator. It does not matter how the *T16\_mCTL.MODEN* and *T16\_mCTL.PRUN* bits of the corresponding 16-bit timer channel are set (1 or 0).

When setting this mode, the timer function of the corresponding 16-bit timer channel may be used for another purpose.

##### Use the 16-bit timer as a baud rate generator

By setting the *SPI*n*MOD.NOCLKDIV* bit to 0, SPIA inputs the underflow signal generated by the corresponding 16-bit timer channel and converts it to the *SPICLK*n**. The 16-bit timer must be run with an appropriate reload data set. The *SPICLK*n** frequency (baud rate) and the 16-bit timer reload data are calculated by the equations shown below.

### 13 SYNCHRONOUS SERIAL INTERFACE (SPIA)

$$f_{\text{SPICLK}} = \frac{f_{\text{CLK\_SPIA}}}{2 \times (\text{RLD} + 1)} \qquad \text{RLD} = \frac{f_{\text{CLK\_SPIA}}}{f_{\text{SPICLK}} \times 2} - 1 \qquad (\text{Eq. 13.1})$$

Where

- $f_{\text{SPICLK}}$ : SPICLK $n$  frequency [Hz] (= baud rate [bps])
- $f_{\text{CLK\_SPIA}}$ : SPIA operating clock frequency [Hz]
- RLD: 16-bit timer reload data value

For controlling the 16-bit timer, refer to the “16-bit Timers” chapter.

#### Operating clock in slave mode

SPIA set in slave mode operates with the clock supplied from the external SPI master to the SPICLK $n$  pin. The 16-bit timer channel (including the clock source selector and the divider) corresponding to the SPIA channel is not used. Furthermore, the SPI $n$ MOD.NOCLKDIV bit setting becomes ineffective.

SPIA keeps operating using the clock supplied from the external SPI master even if all the internal clocks halt during SLEEP mode, so SPIA can receive data and can generate receive buffer full interrupts.

#### 13.3.2 Clock Supply in DEBUG Mode

In master mode, the operating clock supply during DEBUG mode should be controlled using the T16 $_m$ CLK.DB-RUN bit.

The CLK\_T16 $_m$  supply to SPIA Ch. $n$  is suspended when the CPU enters DEBUG mode if the T16 $_m$ CLK.DB-RUN bit = 0. After the CPU returns to normal mode, the CLK\_T16 $_m$  supply resumes. Although SPIA Ch. $n$  stops operating when the CLK\_T16 $_m$  supply is suspended, the output pins and registers retain the status before DEBUG mode was entered. If the T16 $_m$ CLK.DB-RUN bit = 1, the CLK\_T16 $_m$  supply is not suspended and SPIA Ch. $n$  will keep operating in DEBUG mode.

SPIA in slave mode operates with the external SPI master clock input from the SPICLK $n$  pin regardless of whether the CPU is placed into DEBUG mode or normal mode.

#### 13.3.3 SPI Clock (SPICLK $n$ ) Phase and Polarity

The SPICLK $n$  phase and polarity can be configured separately using the SPI $n$ MOD.CPHA bit and the SPI $n$ MOD.CPOL bit, respectively. Figure 13.3.3.1 shows the clock waveform and data input/output timing in each setting.

Figure 13.3.3.1 SPI Clock Phase and Polarity (SPI $n$ MOD.LSBFST bit = 0, SPI $n$ MOD.CHLN[3:0] bits = 0x7)

## 13.4 Data Format

The SPIA data length can be selected from 2 bits to 16 bits by setting the `SPInMOD.CHLN[3:0]` bits. The input/output permutation is configurable to MSB first or LSB first using the `SPInMOD.LSBFST` bit. Figure 13.4.1 shows a data format example when the `SPInMOD.CHLN[3:0]` bits = 0x7, the `SPInMOD.CPOL` bit = 0 and the `SPInMOD.CPHA` bit = 0.

(`SPInMOD.CHLN[3:0]` bits = 0x7, `SPInMOD.CPOL` bit = 0, `SPInMOD.CPHA` bit = 0)

## 13.5 Operations

### 13.5.1 Initialization

SPIA Ch.*n* should be initialized with the procedure shown below.

1. <Master mode only> Generate a clock by controlling the 16-bit timer and supply it to SPIA Ch.*n*.
2. Configure the following `SPInMOD` register bits:
  - `SPInMOD.PUEN` bit (Enable input pin pull-up/down)
  - `SPInMOD.NOCLKDIV` bit (Select master mode operating clock)
  - `SPInMOD.LSBFST` bit (Select MSB first/LSB first)
  - `SPInMOD.CPHA` bit (Select clock phase)
  - `SPInMOD.CPOL` bit (Select clock polarity)
  - `SPInMOD.MST` bit (Select master/slave mode)
3. Assign the SPIA Ch.*n* input/output function to the ports. (Refer to the “I/O Ports” chapter.)
4. Set the following `SPInCTL` register bits:
  - Set the `SPInCTL.SFTRST` bit to 1. (Execute software reset)
  - Set the `SPInCTL.MODEN` bit to 1. (Enable SPIA Ch.*n* operations)
5. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the `SPInINTF` register. (Clear interrupt flags)
  - Set the interrupt enable bits in the `SPInINTE` register to 1. \* (Enable interrupts)

\* The initial value of the `SPInINTF.TBEIF` bit is 1, therefore, an interrupt will occur immediately after the `SPInINTE.TBEIE` bit is set to 1.

### 13.5.2 Data Transmission in Master Mode

A data sending procedure and operations in master mode are shown below. Figures 13.5.2.1 and 13.5.2.2 show a timing chart and a flowchart, respectively.

#### Data sending procedure

1. Assert the slave select signal by controlling the general-purpose output port (if necessary).
2. Check to see if the `SPInINTF.TBEIF` bit is set to 1 (transmit buffer empty).
3. Write transmit data to the `SPInTXD` register.

### 13 SYNCHRONOUS SERIAL INTERFACE (SPIA)

4. Wait for an SPIA interrupt when using the interrupt.
5. Repeat Steps 2 to 4 (or 2 and 3) until the end of transmit data.
6. Negate the slave select signal by controlling the general-purpose output port (if necessary).

#### Data sending operations

SPIA Ch.*n* starts data sending operations when transmit data is written to the SPI*n*TXD register.

The transmit data in the SPI*n*TXD register is automatically transferred to the shift register and the SPI*n*INTF.TBEIF bit is set to 1. If the SPI*n*INTE.TBEIE bit = 1 (transmit buffer empty interrupt enabled), a transmit buffer empty interrupt occurs at the same time.

The SPICLK*n* pin outputs clocks of the number of the bits specified by the SPI*n*MOD.CHLN[3:0] bits and the transmit data bits are output in sequence from the SDO*n* pin in sync with these clocks.

Even if the clock is being output from the SPICLK*n* pin, the next transmit data can be written to the SPI*n*TXD register after making sure the SPI*n*INTF.TBEIF bit is set to 1.

If transmit data has not been written to the SPI*n*TXD register after the last clock is output from the SPICLK*n* pin, the clock output halts and the SPI*n*INTF.TENDIF bit is set to 1. At the same time SPIA issues an end-of-transmission interrupt request if the SPI*n*INTE.TENDIE bit = 1.

### 13.5.3 Data Reception in Master Mode

A data receiving procedure and operations in master mode are shown below. Figures 13.5.3.1 and 13.5.3.2 show a timing chart and flowcharts, respectively.

#### Data receiving procedure

1. Assert the slave select signal by controlling the general-purpose output port (if necessary).
2. Check to see if the  $SPI_nINTF.TBEIF$  bit is set to 1 (transmit buffer empty).
3. Write dummy data (or transmit data) to the  $SPI_nTXD$  register.
4. Wait for a transmit buffer empty interrupt ( $SPI_nINTF.TBEIF$  bit = 1).
5. Write dummy data (or transmit data) to the  $SPI_nTXD$  register.
6. Wait for a receive buffer full interrupt ( $SPI_nINTF.RBFIF$  bit = 1).
7. Read the received data from the  $SPI_nRXD$  register.
8. Repeat Steps 5 to 7 until the end of data reception.
9. Negate the slave select signal by controlling the general-purpose output port (if necessary).

**Note:** To perform continuous data reception without stopping  $SPICLK_n$ , Steps 7 and 5 operations must be completed within the  $SPICLK_n$  cycles equivalent to “Data bit length - 1” after Step 6.

#### Data receiving operations

SPIA Ch. $n$  starts data receiving operations simultaneously with data sending operations when transmit data (may be dummy data if data transmission is not required) is written to the  $SPI_nTXD$  register.

The  $SPICLK_n$  pin outputs clocks of the number of the bits specified by the  $SPI_nMOD.CHLN[3:0]$  bits. The transmit data bits are output in sequence from the  $SDO_n$  pin in sync with these clocks and the receive data bits input from the  $SDI_n$  pin are shifted into the shift register.

When the last clock is output from the  $SPICLK_n$  pin and receive data bits are all shifted into the shift register, the received data is transferred to the receive data buffer and the  $SPI_nINTF.RBFIF$  bit is set to 1. At the same time SPIA issues a receive buffer full interrupt request if the  $SPI_nINTE.RBFIE$  bit = 1. After that, the received data in the receive data buffer can be read through the  $SPI_nRXD$  register.

**Note:** If data of the number of the bits specified by the  $SPI_nMOD.CHLN[3:0]$  bits is received when the  $SPI_nINTF.RBFIF$  bit is set to 1, the  $SPI_nRXD$  register is overwritten with the newly received data and the previously received data is lost. In this case, the  $SPI_nINTF.OEIF$  bit is set.

### 13.5.4 Terminating Data Transfer in Master Mode

A procedure to terminate data transfer in master mode is shown below.

1. Wait for an end-of-transmission interrupt ( $SPI_nINTF.TENDIF$  bit = 1).
2. Set the  $SPI_nCTL.MODEN$  bit to 0 to disable the SPIA Ch. $n$  operations.
3. Stop the 16-bit timer to disable the clock supply to SPIA Ch. $n$ .

### 13.5.5 Data Transfer in Slave Mode

A data sending/receiving procedure and operations in slave mode are shown below. Figures 13.5.5.1 and 13.5.5.2 show a timing chart and flowcharts, respectively.

#### Data sending procedure

1. Check to see if the  $SPI_nINTF.TBEIF$  bit is set to 1 (transmit buffer empty).
2. Write transmit data to the  $SPI_nTXD$  register.
3. Wait for a transmit buffer empty interrupt ( $SPI_nINTF.TBEIF$  bit = 1).
4. Repeat Steps 2 and 3 until the end of transmit data.

**Note:** Transmit data must be written to the  $SPI_nTXD$  register after the  $SPI_nINTF.TBEIF$  bit is set to 1 by the time the sending  $SPI_nTXD$  register data written is completed. If no transmit data is written during this period, the data bits input from the  $SDIn$  pin are shifted and output from the  $SDOn$  pin without being modified.

## Data receiving procedure

1. Wait for a receive buffer full interrupt (SPI $n$ INTF.RBFIF bit = 1).
2. Read the received data from the SPI $n$ RXD register.
3. Repeat Steps 1 and 2 until the end of data reception.

## Data transfer operations

The following shows the slave mode operations different from master mode:

- Slave mode operates with the SPI clock supplied from the external SPI master to the SPICLK $n$  pin.  
The data transfer rate is determined by the SPICLK $n$  frequency. It is not necessary to control the 16-bit timer.
- SPIA can operate as a slave device only when the slave select signal input from the external SPI master to the #SPISS $n$  pin is set to the active (low) level.  
If #SPISS $n$  = high, the software transfer control, the SPICLK $n$  pin input, and the SDI $n$  pin input are all ineffective. If the #SPISS $n$  signal goes high during data transfer, the transfer bit counter is cleared and data in the shift register is discarded.
- Slave mode starts data transfer when SPICLK $n$  is input from the external SPI master after the #SPISS $n$  signal is asserted. Writing transmit data is not a trigger to start data transfer. Therefore, it is not necessary to write dummy data to the transmit data buffer when performing data reception only.
- Data transmission/reception can be performed even in SLEEP mode, it makes it possible to wake the CPU up using an SPIA interrupt.

Other operations are the same as master mode.

- Notes:**
- If data of the number of bits specified by the SPI $n$ MOD.CHLN[3:0] bits is received when the SPI $n$ INTF.RBFIF bit is set to 1, the SPI $n$ RXD register is overwritten with the newly received data and the previously received data is lost. In this case, the SPI $n$ INTF.OEIF bit is set.
  - When the clock for the first bit is input from the SPICLK $n$  pin, SPIA starts sending the data currently stored in the shift register even if the SPI $n$ INTF.TBEIF bit is set to 1.

## 13 SYNCHRONOUS SERIAL INTERFACE (SPIA)

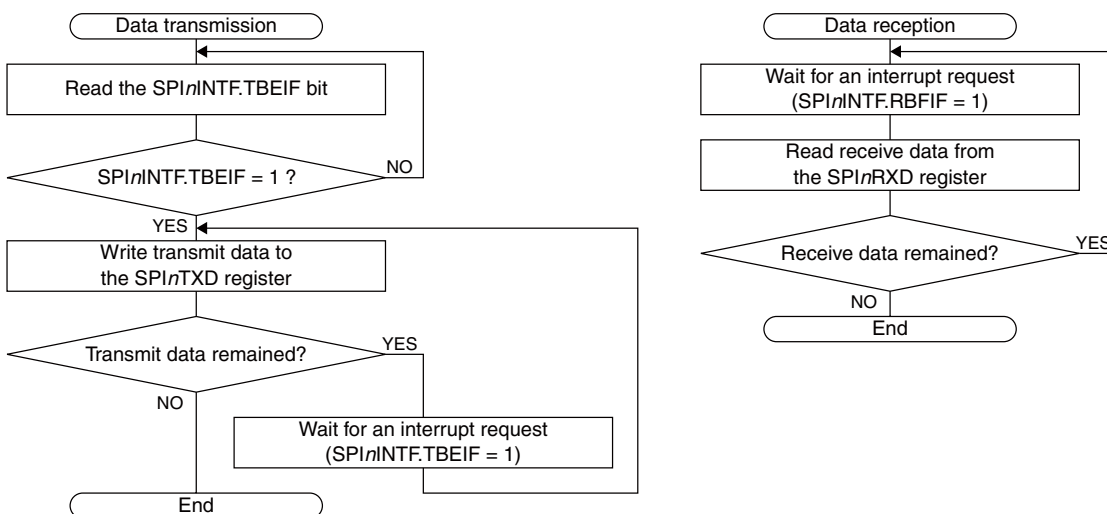

Figure 13.5.5.2 Data Transfer Flowcharts in Slave Mode

### 13.5.6 Terminating Data Transfer in Slave Mode

A procedure to terminate data transfer in slave mode is shown below.

1. Wait for an end-of-transmission interrupt (SPInINTF.TENDIF bit = 1). Or determine end of transfer via the received data.
2. Set the SPInCTL.MODEN bit to 0 to disable the SPIA Ch.n operations.

## 13.6 Interrupts

SPIA has a function to generate the interrupts shown in Table 13.6.1.

Table 13.6.1 SPIA Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
End of transmission	SPInINTF.TENDIF	When the SPInINTF.TBEIF bit = 1 after data of the specified bit length (defined by the SPInMOD.CHLN[3:0] bits) has been sent	Writing 1
Receive buffer full	SPInINTF.RBFIF	When data of the specified bit length is received and the received data is transferred from the shift register to the received data buffer	Reading the SPInRXD register
Transmit buffer empty	SPInINTF.TBEIF	When transmit data written to the transmit data buffer is transferred to the shift register	Writing to the SPInTXD register
Overrun error	SPInINTF.OEIF	When the receive data buffer is full (when the received data has not been read) at the point that receiving data to the shift register has completed	Writing 1

SPIA provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

The SPInINTF register also contains the BSY bit that indicates the SPIA operating status.

Figure 13.6.1 shows the SPInINTF.BSY and SPInINTF.TENDIF bit set timings.

0x4	5 bits
0x3	4 bits
0x2	3 bits
0x1	2 bits
0x0	Setting prohibited

**Bits 7–6 Reserved**

**Bit 5 PUEN**

This bit enables pull-up/down of the input pins.

1 (R/W): Enable pull-up/down

0 (R/W): Disable pull-up/down

For more information, refer to “Input Pin Pull-Up/Pull-Down Function.”

**Bit 4 NOCLKDIV**

This bit selects SPICLK $n$  in master mode. This setting is ineffective in slave mode.

1 (R/W): SPICLK $n$  frequency = CLK\_SPIA $n$  frequency (= 16-bit timer operating clock frequency)

0 (R/W): SPICLK $n$  frequency = 16-bit timer output frequency / 2

For more information, refer to “SPIA Operating Clock.”

**Bit 3 LSBFST**

This bit configures the data format (input/output permutation).

1 (R/W): LSB first

0 (R/W): MSB first

**Bit 2 CPHA**

**Bit 1 CPOL**

These bits set the SPI clock phase and polarity. For more information, refer to “SPI Clock (SPICLK $n$ ) Phase and Polarity.”

**Bit 0 MST**

This bit sets the SPIA operating mode (master mode or slave mode).

1 (R/W): Master mode

0 (R/W): Slave mode

**Note:** The SPI $n$ MOD register settings can be altered only when the SPI $n$ CTL.MODEN bit = 0.

## SPIA Ch. $n$ Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SPI $n$ CTL	15–8	–	0x00	–	R	–
	7–2	–	0x00	–	R	
	1	SFTRST	0	H0	R/W	
	0	MODEN	0	H0	R/W	

**Bits 15–2 Reserved**

**Bit 1 SFTRST**

This bit issues software reset to SPIA.

1 (W): Issue software reset

0 (W): Ineffective

1 (R): Software reset is executing.

0 (R): Software reset has finished. (During normal operation)

Setting this bit resets the SPIA shift register and transfer bit counter. This bit is automatically cleared after the reset processing has finished.

**Bit 0 MODEN**

This bit enables the SPIA operations.

1 (R/W): Enable SPIA operations (In master mode, the operating clock is supplied.)

0 (R/W): Disable SPIA operations (In master mode, the operating clock is stopped.)

**Note:** If the `SPI $n$ CTL.MODEN` bit is altered from 1 to 0 while sending/receiving data, the data being sent/received cannot be guaranteed. When setting the `SPI $n$ CTL.MODEN` bit to 1 again after that, be sure to write 1 to the `SPI $n$ CTL.SFTRST` bit as well.

**SPIA Ch. $n$  Transmit Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
<code>SPI<math>n</math>TXD</code>	15-0	<code>TXD[15:0]</code>	0x0000	H0	R/W	–

**Bits 15-0 TXD[15:0]**

Data can be written to the transmit data buffer through these bits.

In master mode, writing to these bits starts data transfer.

Transmit data can be written when the `SPI $n$ INTF.TBEIF` bit = 1 regardless of whether data is being output from the `SDO $n$`  pin or not.

Note that the upper data bits that exceed the data bit length configured by the `SPI $n$ MOD.CHNLN[3:0]` bits will not be output from the `SDO $n$`  pin.

**Note:** Be sure to avoid writing to the `SPI $n$ TXD` register when the `SPI $n$ INTF.TBEIF` bit = 0. Otherwise, transfer data cannot be guaranteed.

**SPIA Ch. $n$  Receive Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
<code>SPI<math>n</math>RXD</code>	15-0	<code>RXD[15:0]</code>	0x0000	H0	R	–

**Bits 15-0 RXD[15:0]**

The receive data buffer can be read through these bits. Received data can be read when the `SPI $n$ INTF.RBFIF` bit = 1 regardless of whether data is being input from the `SDI $n$`  pin or not. Note that the upper

bits that exceed the data bit length configured by the `SPI $n$ MOD.CHNLN[3:0]` bits become 0.

**Note:** The `SPI $n$ RXD.RXD[15:0]` bits are cleared to 0x0000 when 1 is written to the `SPI $n$ CTL.MODEN` bit or the `SPI $n$ CTL.SFTRST` bit.

# 14 I<sup>2</sup>C (I2C)

## 14.1 Overview

The I2C is a subset of the I<sup>2</sup>C bus interface. The features of the I2C are listed below.

- Functions as an I<sup>2</sup>C bus master (single master) or a slave device.
- Supports standard mode (up to 100 kbit/s) and fast mode (up to 400 kbit/s).
- Supports 7-bit and 10-bit address modes.
- Supports clock stretching.
- Includes a baud rate generator for generating the clock in master mode.
- No clock source is required to run the I2C in slave mode, as it can run with the I<sup>2</sup>C bus signals only.
- Slave mode is capable of being operated in SLEEP mode allowing wake-up by an interrupt when an address match is detected.
- Master mode supports automatic bus clear sending function.
- Can generate receive buffer full, transmit buffer empty, and other interrupts.

Figure 14.1.1 shows the I2C configuration.

## 14.2 Input/Output Pins and External Connections

### 14.2.1 List of Input/Output Pins

Table 14.2.1.1 lists the I<sup>2</sup>C pins.

Table 14.2.1.1 List of I<sup>2</sup>C Pins

Pin name	I/O*	Initial status*	Function
SDA <sub>n</sub>	I/O	I	I <sup>2</sup> C bus serial data input/output pin
SCL <sub>n</sub>	I/O	I	I <sup>2</sup> C bus clock input/output pin

\* Indicates the status when the pin is configured for the I<sup>2</sup>C.

If the port is shared with the I<sup>2</sup>C pin and other functions, the I<sup>2</sup>C input/output function must be assigned to the port before activating the I<sup>2</sup>C. For more information, refer to the “I/O Ports” chapter.

### 14.2.2 External Connections

Figure 14.2.2.1 shows a connection diagram between the I<sup>2</sup>C in this IC and external I<sup>2</sup>C devices.

The serial data (SDA) and serial clock (SCL) lines must be pulled up with an external resistor.

When the I<sup>2</sup>C is set into master mode, one or more slave devices that have a unique address may be connected to the I<sup>2</sup>C bus. When the I<sup>2</sup>C is set into slave mode, one or more master and slave devices that have a unique address may be connected to the I<sup>2</sup>C bus.

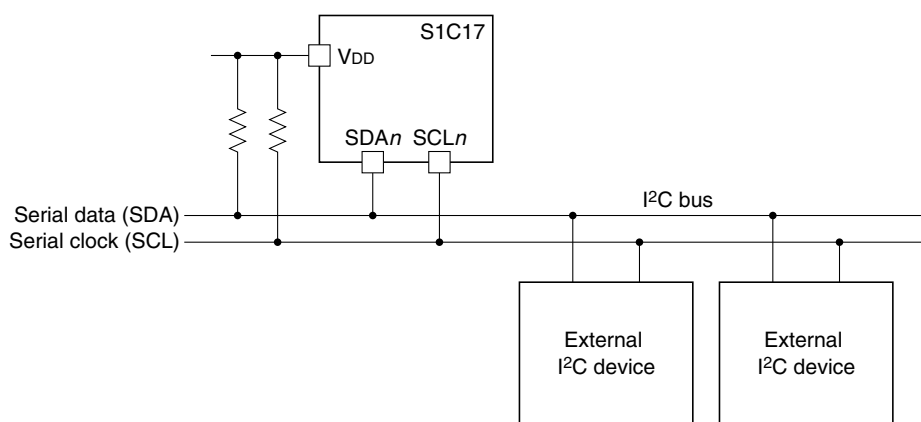

Figure 14.2.2.1 Connections between I<sup>2</sup>C and External I<sup>2</sup>C Devices

- Notes:**
- The SDA and SCL lines must be pulled up to a V<sub>DD</sub> of this IC or lower voltage. However, if the I<sup>2</sup>C input/output ports are configured with the over voltage tolerant fail-safe type I/O, these lines can be pulled up to a voltage exceeding the V<sub>DD</sub> of this IC but within the recommended operating voltage range of this IC.
  - The internal pull-up resistors for the I/O ports cannot be used for pulling up SDA and SCL.
  - When the I<sup>2</sup>C is set into master mode, no other master device can be connected to the I<sup>2</sup>C bus.

## 14.3 Clock Settings

### 14.3.1 I2C Operating Clock

#### Master mode operating clock

When using the I2C Ch.*n* in master mode, the I2C Ch.*n* operating clock CLK\_I2C*n* must be supplied to the I2C Ch.*n* from the clock generator. The CLK\_I2C*n* supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following I2C*n*CLK register bits:
  - I2C*n*CLK.CLKSRC[1:0] bits (Clock source selection)
  - I2C*n*CLK.CLKDIV[1:0] bits (Clock division ratio selection = Clock frequency setting)

When using the I2C in master mode during SLEEP mode, the I2C Ch.*n* operating clock CLK\_I2C*n* must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_I2C*n* clock source.

The I2C operating clock should be selected so that the baud rate generator will be configured easily.

#### Slave mode operating clock

The I2C set to slave mode uses the SCL supplied from the I<sup>2</sup>C master as its operating clock. The clock setting by the I2C*n*CLK register is ineffective.

The I2C keeps operating using the clock supplied from the external I<sup>2</sup>C master even if all the internal clocks halt during SLEEP mode, so the I2C can receive data and can generate receive buffer full interrupts.

### 14.3.2 Clock Supply in DEBUG Mode

In master mode, the CLK\_I2C*n* supply during DEBUG mode should be controlled using the I2C*n*CLK.DBRUN bit. The CLK\_I2C*n* supply to the I2C Ch.*n* is suspended when the CPU enters DEBUG mode if the I2C*n*CLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_I2C*n* supply resumes. Although the I2C Ch.*n* stops operating when the CLK\_I2C*n* supply is suspended, the output pin and registers retain the status before DEBUG mode was entered. If the I2C*n*CLK.DBRUN bit = 1, the CLK\_I2C*n* supply is not suspended and the I2C Ch.*n* will keep operating in DEBUG mode.

In slave mode, the I2C Ch.*n* operates with the external I<sup>2</sup>C master clock input from the SCL*n* pin regardless of whether the CPU is placed into DEBUG mode or normal mode.

### 14.3.3 Baud Rate Generator

The I2C includes a baud rate generator to generate the serial clock SCL used in master mode. The I2C set to slave mode does not use the baud rate generator, as it operates with the serial clock input from the SCL*n* pin.

#### Setting data transfer rate (for master mode)

The transfer rate is determined by the I2C*n*BR.BRT[6:0] bit settings. Use the following equations to calculate the setting values for obtaining the desired transfer rate.

$$\text{bps} = \frac{f_{\text{CLK\_I2C}_n}}{(\text{BRT} + 3) \times 2} \qquad \text{BRT} = \frac{f_{\text{CLK\_I2C}_n}}{\text{bps} \times 2} - 3 \qquad (\text{Eq. 14.1})$$

Where

- bps: Data transfer rate [bit/s]
- f<sub>CLK\_I2C*n*</sub>: I2C operating clock frequency [Hz]
- BRT: I2C*n*BR.BRT[6:0] bits setting value (1 to 127)

\* The equations above do not include SCL rising/falling time and delay time by clock stretching (see Figure 14.3.3.1).

**Note:** The I<sup>2</sup>C bus transfer rate is limited to 100 kbit/s in standard mode or 400 kbit/s in fast mode. Do not set a transfer rate exceeding the limit.

## Baud rate generator clock output and operations for supporting clock stretching

Figure 14.3.3.1 shows the clock generated by the baud rate generator and the clock waveform on the I<sup>2</sup>C bus.

Figure 14.3.3.1 Baud Rate Generator Output Clock and SCL<sub>n</sub> Output Waveform

The baud rate generator output clock SCLO is compared with the SCL<sub>n</sub> pin status and the results are returned to the baud rate generator. If a mismatch has occurred between SCLO and SCL<sub>n</sub> pin levels, the baud rate generator suspends counting. This extends the clock to control data transfer during the SCL signal rising/falling period and clock stretching period in which SCL is fixed at low by a slave device.

## 14.4 Operations

### 14.4.1 Initialization

The I2C Ch.*n* should be initialized with the procedure shown below.

#### When using the I2C in master mode

1. Configure the operating clock and the baud rate generator using the I2C<sub>n</sub>CLK and I2C<sub>n</sub>BR registers.
2. Assign the I2C Ch.*n* input/output function to the ports. (Refer to the “I/O Ports” chapter.)
3. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the I2C<sub>n</sub>INTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the I2C<sub>n</sub>INTE register to 1. (Enable interrupts)
4. Set the following I2C<sub>n</sub>CTL register bits:
  - Set the I2C<sub>n</sub>CTL.MST bit to 1. (Set master mode)
  - Set the I2C<sub>n</sub>CTL.SFTRST bit to 1. (Execute software reset)
  - Set the I2C<sub>n</sub>CTL.MODEN bit to 1. (Enable I2C Ch.*n* operations)

#### When using the I2C in slave mode

1. Set the following I2C<sub>n</sub>MOD register bits:
  - I2C<sub>n</sub>MOD.OADR10 bit (Set 10/7-bit address mode)
  - I2C<sub>n</sub>MOD.GCEN bit (Enable response to general call address)
2. Set its own address to the I2C<sub>n</sub>OADR.OADR[9:0] (or OADR[6:0]) bits.
3. Assign the I2C Ch.*n* input/output function to the ports. (Refer to the “I/O Ports” chapter.)
4. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the I2C<sub>n</sub>INTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the I2C<sub>n</sub>INTE register to 1. (Enable interrupts)
5. Set the following I2C<sub>n</sub>CTL register bits:
  - Set the I2C<sub>n</sub>CTL.MST bit to 0. (Set slave mode)
  - Set the I2C<sub>n</sub>CTL.SFTRST bit to 1. (Execute software reset)
  - Set the I2C<sub>n</sub>CTL.MODEN bit to 1. (Enable I2C Ch.*n* operations)

## 14.4.2 Data Transmission in Master Mode

A data sending procedure in master mode and the I2C Ch.*n* operations are shown below. Figures 14.4.2.1 and 14.4.2.2 show an operation example and a flowchart, respectively.

### Data sending procedure

1. Issue a START condition by setting the I2C*n*CTL.TXSTART bit to 1.
2. Wait for a transmit buffer empty interrupt (I2C*n*INTF.TBEIF bit = 1) or a START condition interrupt (I2C*n*INTF.STARTIF bit = 1).  
Clear the I2C*n*INTF.STARTIF bit by writing 1 after the interrupt has occurred.
3. Write the 7-bit slave address to the I2C*n*TXD.TXD[7:1] bits and 0 that represents WRITE as the data transfer direction to the I2C*n*TXD.TXD0 bit.
4. Wait for a transmit buffer empty interrupt (I2C*n*INTF.TBEIF bit = 1) generated when an ACK is received or a NACK reception interrupt (I2C*n*INTF.NACKIF bit = 1) generated when a NACK is received.
  - i. Go to Step 5 if transmit data remains when a transmit buffer empty interrupt has occurred.
  - ii. Go to Step 7 or 1 after clearing the I2C*n*INTF.NACKIF bit when a NACK reception interrupt has occurred.
5. Write transmit data to the I2C*n*TXD register.
6. Repeat Steps 4 and 5 until the end of transmit data.
7. Issue a STOP condition by setting the I2C*n*CTL.TXSTOP bit to 1.
8. Wait for a STOP condition interrupt (I2C*n*INTF.STOPIF bit = 1).  
Clear the I2C*n*INTF.STOPIF bit by writing 1 after the interrupt has occurred.

### Data sending operations

#### Generating a START condition

The I2C Ch.*n* starts generating a START condition when the I2C*n*CTL.TXSTART bit is set to 1. When the generating operation has completed, the I2C Ch.*n* clears the I2C*n*CTL.TXSTART bit to 0 and sets both the I2C*n*INTF.STARTIF and I2C*n*INTF.TBEIF bits to 1.

#### Sending slave address and data

If the I2C*n*INTF.TBEIF bit = 1, a slave address or data can be written to the I2C*n*TXD register. The I2C Ch.*n* pulls down SCL to low and enters standby state until data is written to the I2C*n*TXD register. The writing operation triggers the I2C Ch.*n* to send the data to the shift register automatically and to output eight clock pulses and data bits to the I<sup>2</sup>C bus.

When the slave device returns an ACK as the response, the I2C*n*INTF.TBEIF bit is set to 1. After this interrupt occurs, the subsequent data may be sent or a STOP/repeated START condition may be issued to terminate transmission. If the slave device returns NACK, the I2C*n*INTF.NACKIF bit is set to 1 without setting the I2C*n*INTF.TBEIF bit.

#### Generating a STOP/repeated START condition

After the I2C*n*INTF.TBEIF bit is set to 1 (transmit buffer empty) or the I2C*n*INTF.NACKIF bit is set to 1 (NACK received), setting the I2C*n*CTL.TXSTOP bit to 1 generates a STOP condition. When the bus free time (t<sub>BUF</sub> defined in the I<sup>2</sup>C Specifications) has elapsed after the STOP condition has been generated, the I2C*n*CTL.TXSTOP bit is cleared to 0 and the I2C*n*INTF.STOPIF bit is set to 1.

When setting the I2C*n*CTL.TXSTART bit to 1 while the I2C*n*INTF.TBEIF bit = 1 (transmit buffer empty) or the I2C*n*INTF.NACKIF bit = 1 (NACK received), the I2C Ch.*n* generates a repeated START condition. When the repeated START condition has been generated, the I2C*n*INTF.STARTIF and I2C*n*INTF.TBEIF bits are both set to 1 same as when a START condition has been generated.

### 14.4.3 Data Reception in Master Mode

A data receiving procedure in master mode and the I2C Ch.*n* operations are shown below. Figures 14.4.3.1 and 14.4.3.2 show an operation example and a flowchart, respectively.

#### Data receiving procedure

1. Issue a START condition by setting the I2C*n*CTL.TXSTART bit to 1.
2. Wait for a transmit buffer empty interrupt (I2C*n*INTF.TBEIF bit = 1) or a START condition interrupt (I2C*n*INTF.STARTIF bit = 1).  
Clear the I2C*n*INTF.STARTIF bit by writing 1 after the interrupt has occurred.
3. Write the 7-bit slave address to the I2C*n*TXD.TXD[7:1] bits and 1 that represents READ as the data transfer direction to the I2C*n*TXD.TXD0 bit.
4. Wait for a receive buffer full interrupt (I2C*n*INTF.RBFIF bit = 1) generated when a one-byte reception has completed or a NACK reception interrupt (I2C*n*INTF.NACKIF bit = 1) generated when a NACK is received.
  - i. Go to Step 5 when a receive buffer full interrupt has occurred.
  - ii. Clear the I2C*n*INTF.NACKIF bit and issue a STOP condition by setting the I2C*n*CTL.TXSTOP bit to 1 when a NACK reception interrupt has occurred. Then go to Step 8 or Step 1 if making a retry.
5. Perform one of the operations below when the last or next-to-last data is received.
  - i. When the next-to-last data is received, write 1 to the I2C*n*CTL.TXNACK bit to send a NACK after the last data is received, and then go to Step 6.
  - ii. When the last data is received, read the received data from the I2C*n*RXD register and set the I2C*n*CTL.TXSTOP to 1 to generate a STOP condition. Then go to Step 8.
6. Read the received data from the I2C*n*RXD register.
7. Repeat Steps 4 to 6 until the end of data reception.
8. Wait for a STOP condition interrupt (I2C*n*INTF.STOIF bit = 1).  
Clear the I2C*n*INTF.STOIF bit by writing 1 after the interrupt has occurred.

#### Data receiving operations

##### Generating a START condition

It is the same as the data transmission in master mode.

##### Sending slave address

It is the same as the data transmission in master mode. Note, however, that the I2C*n*TXD.TXD0 bit must be set to 1 that represents READ as the data transfer direction to issue a request to the slave to send data.

##### Receiving data

After the slave address has been sent, the slave device sends an ACK and the first data. The I2C Ch.*n* sets the I2C*n*INTF.RBFIF bit to 1 after the data reception has completed. Furthermore, the I2C Ch.*n* returns an ACK. To return a NACK, such as for a response after the last data has been received, write 1 to the I2C*n*CTL.TXNACK bit before the I2C*n*INTF.RBFIF bit is set to 1.

The received data can be read out from the I2C*n*RXD register after a receive buffer full interrupt has occurred. The I2C Ch.*n* pulls down SCL to low and enters standby state until data is read out from the I2C*n*RXD register.

This reading triggers the I2C Ch.*n* to start subsequent data reception.

##### Generating a STOP or repeated START condition

It is the same as the data transmission in master mode.

### 14.4.4 10-bit Addressing in Master Mode

A 10-bit address consists of the first address that contains two high-order bits and the second address that contains eight low-order bits.

7-bit address

10-bit address

Figure 14.4.4.1 10-bit Address Configuration

The following shows a procedure to start data transfer in 10-bit address mode when the I2C Ch.*n* is placed into master mode (see the 7-bit mode descriptions above for control procedures when a NACK is received or sending/receiving data). Figure 14.4.4.2 shows an operation example.

#### Starting data transmission in 10-bit address mode

1. Issue a START condition by setting the I2C<sub>n</sub>CTL.TXSTART bit to 1.
2. Wait for a transmit buffer empty interrupt (I2C<sub>n</sub>INTF.TBEIF bit = 1) or a START condition interrupt (I2C<sub>n</sub>INTF.STARTIF bit = 1).  
Clear the I2C<sub>n</sub>INTF.STARTIF bit by writing 1 after the interrupt has occurred.
3. Write the first address to the I2C<sub>n</sub>TXD.TXD[7:1] bits and 0 that represents WRITE as the data transfer direction to the I2C<sub>n</sub>TXD.TXD0 bit.
4. Wait for a transmit buffer empty interrupt (I2C<sub>n</sub>INTF.TBEIF bit = 1).
5. Write the second address to the I2C<sub>n</sub>TXD.TXD[7:0] bits.
6. Wait for a transmit buffer empty interrupt (I2C<sub>n</sub>INTF.TBEIF bit = 1).
7. Perform data transmission.

#### Starting data reception in 10-bit address mode

- 1 to 6. These steps are the same as the data transmission starting procedure described above.
7. Issue a repeated START condition by setting the I2C<sub>n</sub>CTL.TXSTART bit to 1.
8. Wait for a transmit buffer empty interrupt (I2C<sub>n</sub>INTF.TBEIF bit = 1) or a START condition interrupt (I2C<sub>n</sub>INTF.STARTIF bit = 1).  
Clear the I2C<sub>n</sub>INTF.STARTIF bit by writing 1 after the interrupt has occurred.
9. Write the first address to the I2C<sub>n</sub>TXD.TXD[7:1] bits and 1 that represents READ as the data transfer direction to the I2C<sub>n</sub>TXD.TXD0 bit.
10. Perform data reception.

### 14.4.5 Data Transmission in Slave Mode

A data sending procedure in slave mode and the I2C Ch.*n* operations are shown below. Figures 14.4.5.1 and 14.4.5.2 show an operation example and a flowchart, respectively.

#### Data sending procedure

1. Wait for a START condition interrupt (I2C*n*INTF.STARTIF bit = 1).  
Clear the I2C*n*INTF.STARTIF bit by writing 1 after the interrupt has occurred.
2. Check to see if the I2C*n*INTF.TR bit = 1 (transmission mode).  
(Start a data receiving procedure if the I2C*n*INTF.TR bit = 0.)
3. Write transmit data to the I2C*n*TXD register.
4. Wait for a transmit buffer empty interrupt (I2C*n*INTF.TBEIF bit = 1), a NACK reception interrupt (I2C*n*INTF.NACKIF bit = 1), or a STOP condition interrupt (I2C*n*INTF.STOPIF bit = 1).
  - i. Go to Step 3 when a transmit buffer empty interrupt has occurred.
  - ii. Go to Step 5 after clearing the I2C*n*INTF.NACKIF bit when a NACK reception interrupt has occurred.
  - iii. Go to Step 6 when a STOP condition interrupt has occurred.
5. Wait for a STOP condition interrupt (I2C*n*INTF.STOPIF bit = 1) or a START condition interrupt (I2C*n*INTF.STARTIF bit = 1).
  - i. Go to Step 6 when a STOP condition interrupt has occurred.
  - ii. Go to Step 2 when a START condition interrupt has occurred.
6. Clear the I2C*n*INTF.STOPIF bit and then terminate data sending operations.

## Data sending operations

### START condition detection and slave address check

While the I2CnCTL.MODEN bit = 1 and the I2CnCTL.MST bit = 0 (slave mode), the I2C Ch.n monitors the I<sup>2</sup>C bus. When the I2C Ch.n detects a START condition, it starts receiving of the slave address sent from the master. If the received address is matched with the own address set to the I2CnOADR.OADR[6:0] bits (when the I2CnMOD.OADR10 bit = 0 (7-bit address mode)) or the I2CnOADR.OADR[9:0] bits (when the I2CnMOD.OADR10 bit = 1 (10-bit address mode)), the I2CnINTF.STARTIF bit and the I2CnINTF.BSY bit are both set to 1. The I2C Ch.n sets the I2CnINTF.TR bit to the R/W bit value in the received address. If this value is 1, the I2C Ch.n sets the I2CnINTF.TBEIF bit to 1 and starts data sending operations.

### Sending the first data byte

After the valid slave address has been received, the I2C Ch.n pulls down SCL to low and enters standby state until data is written to the I2CnTXD register. This puts the I<sup>2</sup>C bus into clock stretching state and the external master into standby state. When transmit data is written to the I2CnTXD register, the I2C Ch.n clears the I2CnINTF.TBEIF bit and sends an ACK to the master. The transmit data written in the I2CnTXD register is automatically transferred to the shift register and the I2CnINTF.TBEIF bit is set to 1. The data bits in the shift register are output in sequence to the I<sup>2</sup>C bus.

### Sending subsequent data

If the I2CnINTF.TBEIF bit = 1, subsequent transmit data can be written during data transmission. If the I2CnINTF.TBEIF bit is still set to 1 when the data transmission from the shift register has completed, the I2C Ch.n pulls down SCL to low (sets the I<sup>2</sup>C bus into clock stretching state) until transmit data is written to the I2CnTXD register.

If the next transmit data already exists in the I2CnTXD register or data has been written after the above, the I2C Ch.n sends the subsequent eight-bit data when an ACK from the external master is received. At the same time, the I2CnINTF.BYTEENDIF bit is set to 1. If a NACK is received, the I2CnINTF.NACKIF bit is set to 1 without sending data.

### STOP/repeated START condition detection

While the I2CnCTL.MST bit = 0 (slave mode) and the I2CnINTF.BSY = 1, the I2C Ch.n monitors the I<sup>2</sup>C bus. When the I2C Ch.n detects a STOP condition, it terminates data sending operations. At this time, the I2CnINTF.BSY bit is cleared to 0 and the I2CnINTF.STOPIF bit is set to 1. Also when the I2C Ch.n detects a repeated START condition, it terminates data sending operations. In this case, the I2CnINTF.STARTIF bit is set to 1.

## 14.4.6 Data Reception in Slave Mode

A data receiving procedure in slave mode and the I2C Ch.n operations are shown below. Figures 14.4.6.1 and 14.4.6.2 show an operation example and a flowchart, respectively.

### Data receiving procedure

1. Wait for a START condition interrupt (I2CnINTF.STARTIF bit = 1).
2. Check to see if the I2CnINTF.TR bit = 0 (reception mode).  
(Start a data sending procedure if I2CnINTF.TR bit = 1.)
3. Clear the I2CnINTF.STARTIF bit by writing 1.
4. Wait for a receive buffer full interrupt (I2CnINTF.RBFIF bit = 1) generated when a one-byte reception has completed or an end of transfer interrupt (I2CnINTF.BYTEENDIF bit = 1).  
Clear the I2CnINTF.BYTEENDIF bit by writing 1 after the interrupt has occurred.
5. If the next receive data is the last one, write 1 to the I2CnCTL.TXNACK bit to send a NACK after it is received.
6. Read the received data from the I2CnRXD register.
7. Repeat Steps 4 to 6 until the end of data reception.
8. Wait for a STOP condition interrupt (I2CnINTF.STOPIF bit = 1) or a START condition interrupt (I2CnINTF.STARTIF bit = 1).
  - i. Go to Step 9 when a STOP condition interrupt has occurred.
  - ii. Go to Step 2 when a START condition interrupt has occurred.
9. Clear the I2CnINTF.STOPIF bit and then terminate data receiving operations.

### Data receiving operations

#### START condition detection and slave address check

It is the same as the data transmission in slave mode.

However, the I2CnINTF.TR bit is cleared to 0 and the I2CnINTF.TBEIF bit is not set.

If the I2CnMOD.GCEN bit is set to 1 (general call address response enabled), the I2C Ch.n starts data receiving operations when the general call address is received.

Slave mode can be operated even in SLEEP mode, it makes it possible to wake the CPU up using an interrupt when an address match is detected.

#### Receiving the first data byte

After the valid slave address has been received, the I2C Ch.n sends an ACK and pulls down SCL to low until 1 is written to the I2CnINTF.STARTIF bit. This puts the I<sup>2</sup>C bus into clock stretching state and the external master into standby state. When 1 is written to the I2CnINTF.STARTIF bit, the I2C Ch.n releases SCL and receives data sent from the external master into the shift register. After eight-bit data has been received, the I2C Ch.n sends an ACK and pulls down SCL to low. The received data in the shift register is transferred to the receive data buffer and the I2CnINTF.RBFIF and I2CnINTF.BYTEENDIF bits are both set to 1. After that, the received data can be read out from the I2CnRXD register.

### Receiving subsequent data

When the received data is read out from the I2CnRXD register after the I2CnINTF.RBFIF bit has been set to 1, the I2C Ch.n clears the I2CnINTF.RBFIF bit to 0, releases SCL, and receives subsequent data sent from the external master. After eight-bit data has been received, the I2C Ch.n sends an ACK and pulls down SCL to low. The received data in the shift register is transferred to the receive data buffer and the I2CnINTF.RBFIF and I2CnINTF.BYTEENDIF bits are both set to 1.

To return a NACK after eight-bit data is received, such as when terminating data reception, write 1 to the I2CnCTL.TXNACK bit before the data reception is completed. The I2CnCTL.TXNACK bit is automatically cleared to 0 after a NACK has been sent.

### STOP/repeated START condition detection

It is the same as the data transmission in slave mode.

Figure 14.4.6.1 Example of Data Receiving Operations in Slave Mode

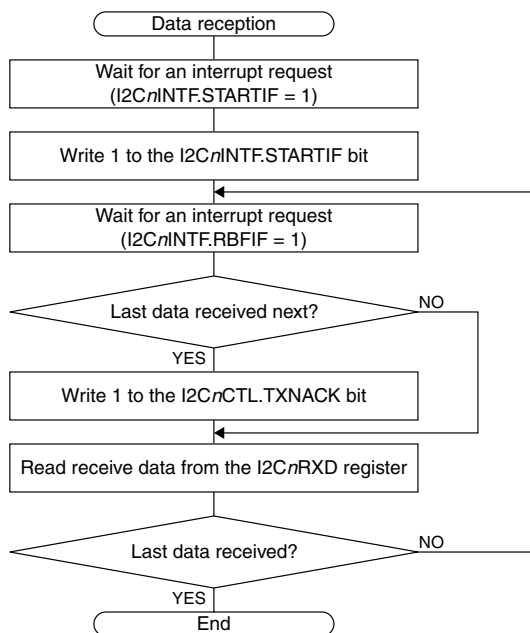

Figure 14.4.6.2 Slave Mode Data Reception Flowchart

### 14.4.7 Slave Operations in 10-bit Address Mode

The I2C Ch.*n* functions as a slave device in 10-bit address mode when the I2CnCTL.MST bit = 0 and the I2CnMOD.OADR10 bit = 1.

The following shows the address receiving operations in 10-bit address mode. Figure 14.4.7.1 shows an operation example. See Figure 14.4.4.1 for the 10-bit address configuration.

#### 10-bit address receiving operations

After a START condition is issued, the master sends the first address that includes the two high-order slave address bits and the R/W bit (= 0). If the received two high-order slave address bits are matched with the I2CnOADR.OADR[9:8] bits, the I2C Ch.*n* returns an ACK. At this time, other slaves may return an ACK as the two high-order bits may be matched.

Then the master sends the eight low-order slave address bits as the second address. If this address is matched with the I2CnOADR.OADR[7:0] bits, the I2C Ch.*n* returns an ACK and starts data receiving operations.

If the master issues a request to the slave to send data (data reception in the master), the master generates a repeated START condition and sends the first address with the R/W bit set to 1. This reception switches the I2C Ch.*n* to data sending mode.

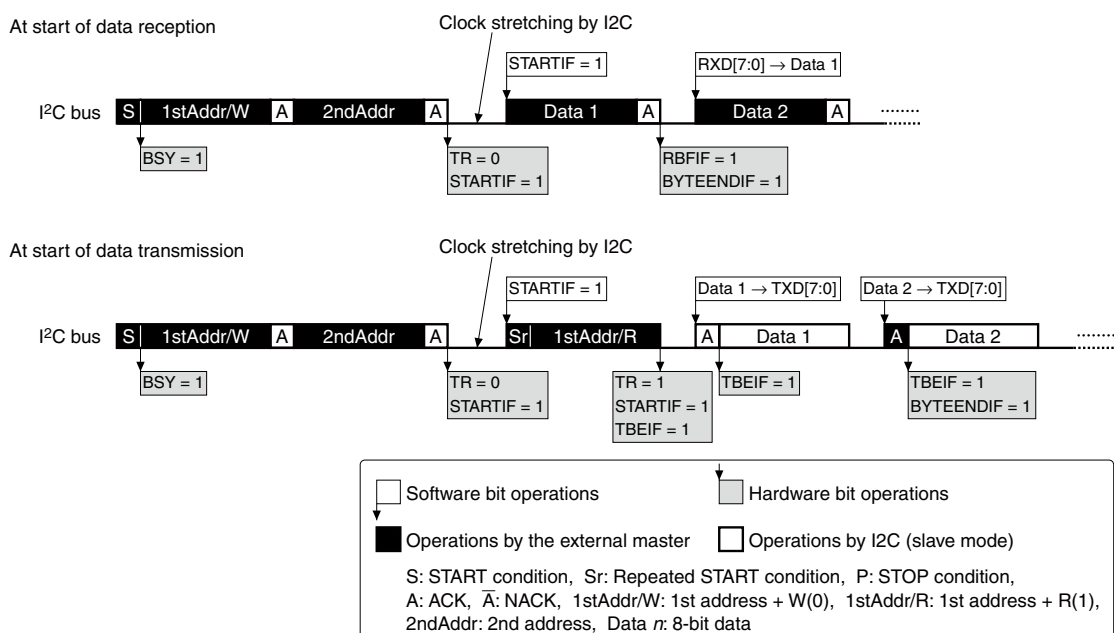

Figure 14.4.7.1 Example of Data Transfer Starting Operations in 10-bit Address Mode (Slave Mode)

### 14.4.8 Automatic Bus Clearing Operation

The I2C Ch.*n* set into master mode checks the SDA state immediately before generating a START condition. If SDA is set to a low level at this time, the I2C Ch.*n* automatically executes bus clearing operations that output up to ten clocks from the SCL<sub>*n*</sub> pin with SDA left free state.

When SDA goes high from low within nine clocks, the I2C Ch.*n* issues a START condition and starts normal operations. If SDA does not change from low when the I2C Ch.*n* outputs the ninth clock, it is regarded as an automatic bus clearing failure. In this case, the I2C Ch.*n* clears the I2CnCTL.TXSTART bit to 0 and sets both the I2CnINTF.ERRIF and I2CnINTF.STARTIF bits to 1.

Figure 14.4.8.1 Automatic Bus Clearing Operation

## 14.4.9 Error Detection

The I<sup>2</sup>C includes a hardware error detection function.

Furthermore, the I2CnINTF.SDALOW and I2CnINTF.SCLLOW bits are provided to allow software to check whether the SDA and SCL lines are fixed at low. If unintended low level is detected on SDA or SCL, a software recovery processing, such as I2C Ch.n software reset, can be performed.

The table below lists the hardware error detection conditions and the notification method.

Table 14.4.9.1 Hardware Error Detection Function

No.	Error detecting period/timing	I <sup>2</sup> C bus line monitored and error condition	Notification method
1	While the I2C Ch.n controls SDA to high for sending address, data, or a NACK	SDA = low	I2CnINTF.ERRIF = 1
2	<Master mode only> When 1 is written to the I2CnCTL.TX-START bit while the I2CnINTF.BSY bit = 0	SCL = low	I2CnINTF.ERRIF = 1 I2CnCTL.TXSTART = 0 I2CnINTF.STARTIF = 1
3	<Master mode only> When 1 is written to the I2CnCTL.TXSTOP bit while the I2CnINTF.BSY bit = 0	SCL = low	I2CnINTF.ERRIF = 1 I2CnCTL.TXSTOP = 0 I2CnINTF.STOPIF = 1
4	<Master mode only> When 1 is written to the I2CnCTL.TX-START bit while the I2CnINTF.BSY bit = 0 (Refer to “Automatic Bus Clearing Operation.”)	SDA Automatic bus clearing failure	I2CnINTF.ERRIF = 1 I2CnCTL.TXSTART = 0 I2CnINTF.STARTIF = 1

## 14.5 Interrupts

The I2C has a function to generate the interrupts shown in Table 14.5.1.

Table 14.5.1 I2C Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
End of data transfer	I2CnINTF.BYTEENDIF	When eight-bit data transfer and the following ACK/NACK transfer are completed	Writing 1, software reset
General call address reception	I2CnINTF.GCIF	Slave mode only: When the general call address is received	Writing 1, software reset
NACK reception	I2CnINTF.NACKIF	When a NACK is received	Writing 1, software reset
STOP condition	I2CnINTF.STOPIF	Master mode: When a STOP condition is generated and the bus free time ( $t_{BUF}$ ) between STOP and START conditions has elapsed  Slave mode: When a STOP condition is detected while the I2C Ch.n is selected as the slave currently accessed	Writing 1, software reset
START condition	I2CnINTF.STARTIF	Master mode: When a START condition is issued  Slave mode: When an address match is detected (including general call)	Writing 1, software reset
Error detection	I2CnINTF.ERRIF	Refer to “Error Detection.”	Writing 1, software reset
Receive buffer full	I2CnINTF.RBFIF	When received data is loaded to the receive data buffer	Reading received data (to empty the receive data buffer), software reset
Transmit buffer empty	I2CnINTF.TBEIF	Master mode: When a START condition is issued or when an ACK is received from the slave  Slave mode: When transmit data written to the transmit data buffer is transferred to the shift register or when an address match is detected with R/W bit set to 1	Writing transmit data

The I2C provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

#### Bits 15–9 Reserved

#### Bit 8 DBRUN

This bit sets whether the I2C operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

#### Bits 7–6 Reserved

#### Bits 5–4 CLKDIV[1:0]

These bits select the division ratio of the I2C operating clock.

#### Bits 3–2 Reserved

#### Bits 1–0 CLKSRC[1:0]

These bits select the clock source of the I2C.

	2	OADR10	0	H0	R/W	
	1	GCEN	0	H0	R/W	
	0	–	0	–	R	

### Bits 15–3 Reserved

#### Bit 2 OADR10

This bit sets the number of own address bits for slave mode.

1 (R/W): 10-bit address

0 (R/W): 7-bit address

#### Bit 1 GCEN

This bit sets whether to respond to master general calls in slave mode or not.

1 (R/W): Respond to general calls.

0 (R/W): Do not respond to general calls.

#### Bit 0 Reserved

**Note:** The I2CnMOD register settings can be altered only when the I2CnCTL.MODEN bit = 0.

## I2C Ch.n Baud-Rate Register

I2CnBR	15–8	–	0x00	–	R	–
	7	–	0	–	R	
	6–0	BRT[6:0]	0x7f	H0	R/W	

### Bits 15–7 Reserved

#### Bits 6–0 BRT[6:0]

These bits set the I2C Ch.n transfer rate for master mode. For more information, refer to “Baud Rate Generator.”

**Notes:** • The I2CnBR register settings can be altered only when the I2CnCTL.MODEN bit = 0.

- Be sure to avoid setting the I2CnBR register to 0.

## I2C Ch.n Own Address Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
I2CnOADR	15–10	–	0x00	–	R	–
	9–0	OADR[9:0]	0x000	H0	R/W	

### Bits 15–10 Reserved

#### Bits 9–0 OADR[9:0]

These bits set the own address for slave mode.

The I2CnOADR.OADR[9:0] bits are effective in 10-bit address mode (I2CnMOD.OADR10 bit = 1), or the I2CnOADR.OADR[6:0] bits are effective in 7-bit address mode (I2CnMOD.OADR10 bit = 0).

**Note:** The I2CnOADR register settings can be altered only when the I2CnCTL.MODEN bit = 0.

## I2C Ch.n Control Register

	1	SFTRST	0	H0	R/W	
	0	MODEN	0	H0	R/W	

### Bits 15–6 Reserved

#### Bit 5 MST

This bit selects the I2C Ch.n operating mode.

1 (R/W): Master mode

0 (R/W): Slave mode

#### Bit 4 TXNACK

This bit issues a request for sending a NACK at the next responding.

1 (W): Issue a NACK.

0 (W): Ineffective

1 (R): On standby or during sending a NACK

0 (R): NACK has been sent.

This bit is automatically cleared after a NACK has been sent.

#### Bit 3 TXSTOP

This bit issues a STOP condition in master mode. This bit is ineffective in slave mode.

1 (W): Issue a STOP condition.

0 (W): Ineffective

1 (R): On standby or during generating a STOP condition

0 (R): STOP condition has been generated.

This bit is automatically cleared when the bus free time ( $t_{BUF}$  defined in the I<sup>2</sup>C Specifications) has elapsed after the STOP condition has been generated.

#### Bit 2 TXSTART

This bit issues a START condition in master mode. This bit is ineffective in slave mode.

1 (W): Issue a START condition.

0 (W): Ineffective

1 (R): On standby or during generating a START condition

0 (R): START condition has been generated.

This bit is automatically cleared when a START condition has been generated.

#### Bit 1 SFTRST

This bit issues software reset to the I2C.

1 (W): Issue software reset

0 (W): Ineffective

1 (R): Software reset is executing.

0 (R): Software reset has finished. (During normal operation)

Setting this bit resets the I2C transmit/receive control circuit and interrupt flags. This bit is automatically cleared after the reset processing has finished.

#### Bit 0 MODEN

This bit enables the I2C operations.

1 (R/W): Enable I2C operations (The operating clock is supplied.)

0 (R/W): Disable I2C operations (The operating clock is stopped.)

**Note:** If the I2CnCTL.MODEN bit is altered from 1 to 0 while sending/receiving data, the data being sent/received cannot be guaranteed. When setting the I2CnCTL.MODEN bit to 1 again after that, be sure to write 1 to the I2CnCTL.SFTRST bit as well.

### I2C Ch.n Transmit Data Register

# 15 16-bit PWM Timers (T16B)

## 15.1 Overview

T16B is a 16-bit PWM timer with comparator/capture functions. The features of T16B are listed below.

- Counter block
  - 16-bit up/down counter
  - A clock source and a clock division ratio for generating the count clock are selectable in each channel.
  - The count mode is configurable from combinations of up, down, or up/down count operations, and one-shot operations (counting for one cycle configured) or repeat operations (counting continuously until stopped via software).
  - Supports an event counter function using an external clock.
- Comparator/capture block
  - Supports up to six comparator/capture circuits to be included per one channel.
  - The comparator compares the counter value with the values specified via software to generate interrupt signals and a PWM waveform. (Can be used as an interval timer, PWM waveform generator, and external event counter.)
  - The capture circuit captures counter values using external/software trigger signals and generates interrupts. (Can be used to measure external event periods/cycles.)

Figure 15.1.1 shows the T16B configuration.

Table 15.1.1 T16B Channel Configuration of S1C17W03/W04

Item	32-pin package	48-pin package/chip
Number of channels	2 channels (Ch.0 and Ch.1)	
Event counter function	Ch.0: EXCL00 or EXCL01 pin input Ch.1: EXCL10 or EXCL11 pin input	
Number of comparator/capture circuits per channel	2 systems (0 and 1)	
Timer generating signal output	Ch.0: TOUT00 and TOUT01 pin outputs (2 systems) Ch.1: TOUT10 and TOUT11 pin outputs (2 systems)	
Capture signal input	Ch.0: CAP00 and CAP01 pin inputs (2 systems) Ch.1: CAP10 and CAP11 pin inputs (2 systems)	

**Note:** In this chapter, 'n' refers to a channel number, and 'm' refers to an input/output pin number or a comparator/capture circuit number in a channel.

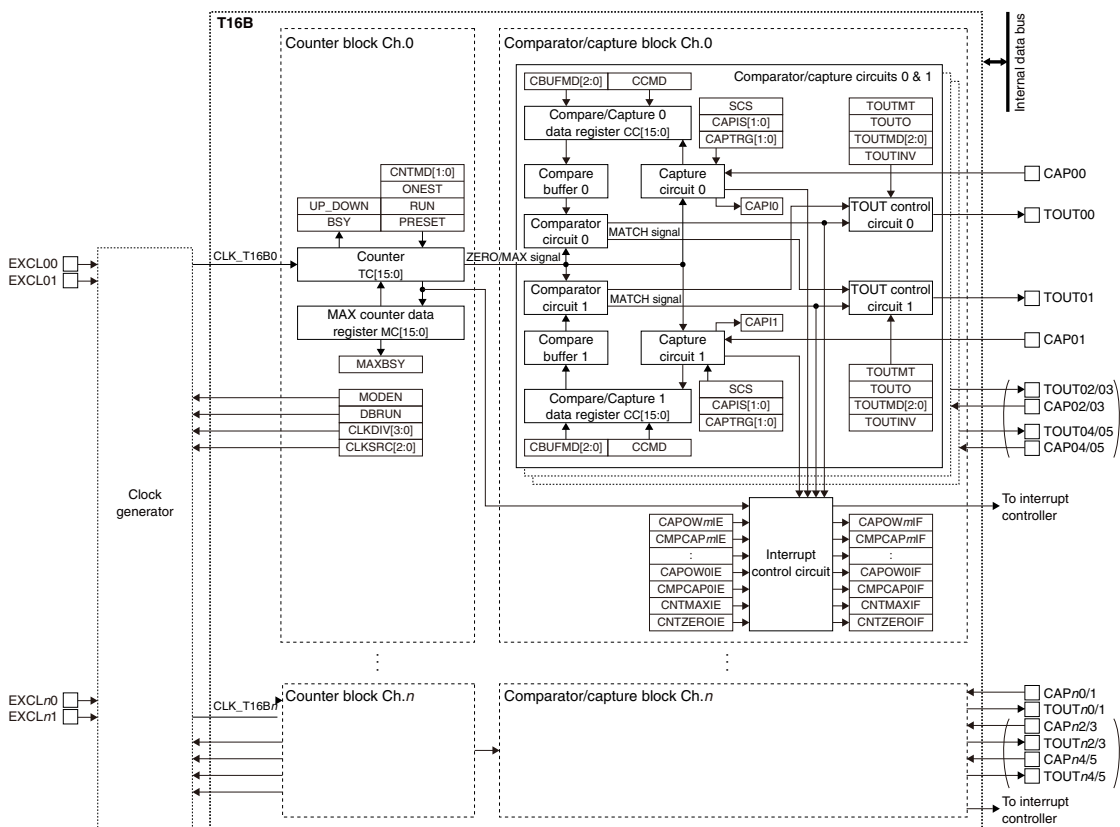

Figure 15.1.1 T16B Configuration

## 15.2 Input/Output Pins

Table 15.2.1 lists the T16B pins.

Table 15.2.1 List of T16B Pins

Pin name	I/O*	Initial status*	Function
EXCL $n$ m	I	I (Hi-Z)	External clock input
TOUT $n$ m/CAP $n$ m	O or I	O (L)	TOUT signal output (in comparator mode) or capture trigger signal input (in capture mode)

\* Indicates the status when the pin is configured for T16B.

If the port is shared with the T16B pin and other functions, the T16B input/output function must be assigned to the port before activating T16B. For more information, refer to the “I/O Ports” chapter.

## 15.3 Clock Settings

### 15.3.1 T16B Operating Clock

When using T16B Ch.*n*, the T16B Ch.*n* operating clock CLK\_T16B*n* must be supplied to T16B Ch.*n* from the clock generator. The CLK\_T16B*n* supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).

When an external clock is used, select the EXCL*nm* pin function (refer to the “I/O Ports” chapter).

2. Set the following T16B*n*CLK register bits:
  - T16B*n*CLK.CLKSRC[2:0] bits (Clock source selection)
  - T16B*n*CLK.CLKDIV[3:0] bits (Clock division ratio selection = Clock frequency setting)

### 15.3.2 Clock Supply in SLEEP Mode

When using T16B during SLEEP mode, the T16B operating clock CLK\_T16B*n* must be configured so that it will keep supplying by writing 0 to the CLGOSC.*xxxx*SLPC bit for the CLK\_T16B*n* clock source.

If the CLGOSC.*xxxx*SLPC bit for the CLK\_T16B*n* clock source is 1, the CLK\_T16B*n* clock source is deactivated during SLEEP mode and T16B stops with the register settings and counter value maintained at those before entering SLEEP mode. After the CPU returns to normal mode, CLK\_T16B*n* is supplied and the T16B operation resumes.

### 15.3.3 Clock Supply in DEBUG Mode

The CLK\_T16B*n* supply during DEBUG mode should be controlled using the T16B*n*CLK.DBRUN bit.

The CLK\_T16B*n* supply to T16B Ch.*n* is suspended when the CPU enters DEBUG mode if the T16B*n*CLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_T16B*n* supply resumes. Although T16B Ch.*n* stops operating when the CLK\_T16B*n* supply is suspended, the counter and registers retain the status before DEBUG mode was entered. If the T16B*n*CLK.DBRUN bit = 1, the CLK\_T16B*n* supply is not suspended and T16B Ch.*n* will keep operating in DEBUG mode.

### 15.3.4 Event Counter Clock

When EXCL*nm* is selected as the clock source using the T16B*n*CLK.CLKSRC[2:0] bits, the channel functions as a timer or event counter that counts the EXCL*nm* pin input clocks.

The counter counts rising edges of the input signal. This can be changed so that the counter will count falling edges of the original signal by selecting EXCL*nm* inverted input as the clock source.

Figure 15.3.4.1 Count Timing (During Count Up Operation)

**Note:** When running the counter using the event counter clock, two dummy clocks must be input before the first counting up/down can be performed.

## 15.4 Operations

---

### 15.4.1 Initialization

T16B Ch.*n* should be initialized and started counting with the procedure shown below. Perform initial settings for comparator mode when using T16B as an interval timer, PWM waveform generator, or external event counter. Perform initial settings for capture mode when using T16B to measure external event periods/cycles.

#### Initial settings for comparator mode

1. Configure the T16B Ch.*n* operating clock.
2. Set the T16B*n*CTL.MODEN bit to 1. (Enable T16B operations)
3. Set the following T16B*n*CCCTL0 and T16B*n*CCCTL1 register bits:
  - Set the T16B*n*CCCTL*m*.CCMD bit to 0. \* (Set comparator mode)
  - T16B*n*CCCTL*m*.CBUFMD[2:0] bits (Configure compare buffer)
 \* Another circuit in the comparator/capture circuit pair (circuits 0 and 1, 2 and 3, 4 and 5) can be set to capture mode.
- Set the following bits when the TOUT*nm* output is used.
  - T16B*n*CCCTL*m*.TOUTMT bit (Select waveform generation signal)
  - T16B*n*CCCTL*m*.TOUTMD[2:0] bits (Select TOUT signal generation mode)
  - T16B*n*CCCTL*m*.TOUTINV bit (Select TOUT signal polarity)
4. Set the T16B*n*MC register. (Set MAX counter data)
5. Set the T16B*n*CCR0 and T16B*n*CCR1 registers. (Set the counter comparison value)
6. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the T16B*n*INTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the T16B*n*INTE register to 1. (Enable interrupts)
7. Set the following T16B*n*CTL register bits:
  - T16B*n*CTL.CNTMD[1:0] bits (Select count up/down operation)
  - T16B*n*CTL.ONEST bit (Select one-shot/repeat operation)
  - Set the T16B*n*CTL.PRESET bit to 1. (Reset counter)
  - Set the T16B*n*CTL.RUN bit to 1. (Start counting)

#### Initial settings for capture mode

1. Configure the T16B Ch.*n* operating clock.
2. Set the T16B*n*CTL.MODEN bit to 1. (Enable T16B operations)
3. Set the following T16B*n*CCCTL0 and T16B*n*CCCTL1 register bits:
  - Set the T16B*n*CCCTL*m*.CCMD bit to 1. \* (Set capture mode)
  - T16B*n*CCCTL*m*.SCS bit (Set synchronous/asynchronous mode)
  - T16B*n*CCCTL*m*.CAPIS[1:0] bits (Set trigger signal)
  - T16B*n*CCCTL*m*.CAPTRG[1:0] bits (Select trigger edge)
 \* Another circuit in the comparator/capture circuit pair (circuits 0 and 1, 2 and 3, 4 and 5) can be set to comparator mode.
4. Set the T16B*n*MC register. (Set MAX counter data)
5. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the T16B*n*INTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the T16B*n*INTE register to 1. (Enable interrupts)
6. Set the following T16B*n*CTL register bits:
  - T16B*n*CTL.CNTMD[1:0] bits (Select count up/down operation)
  - T16B*n*CTL.ONEST bit (Select one-shot/repeat operation)
  - Set the T16B*n*CTL.PRESET bit to 1. (Reset counter)
  - Set the T16B*n*CTL.RUN bit to 1. (Start counting)

## 15.4.2 Counter Block Operations

The counter in each counter block channel is a 16-bit up/down counter that counts the selected operating clock (count clock).

### Count mode

The T16B $n$ CTL.CNTMD[1:0] bits allow selection of up, down, and up/down mode. The T16B $n$ CTL.ONEST bit allows selection of repeat and one-shot mode. The counter operates in six counter modes specified with a combination of these modes.

Repeat mode enables the counter to continue counting until stopped via software. Select this mode to generate periodic interrupts at desired intervals or to generate timer output waveforms.

One-shot mode enables the counter to stop automatically. Select this mode to stop the counter after an interrupt has occurred once, such as for measuring pulse width or external event intervals and checking a specific lapse of time.

Up, down, and up/down mode configures the counter as an up counter, down counter and up/down counter, respectively.

### MAX counter data register

The MAX counter data register (T16B $n$ MC.MC[15:0] bits) is used to set the maximum value of the counter (hereafter referred to as MAX value). This setting limits the count range to 0x0000–MAX value and determines the count and interrupt cycles. When the counter is set to repeat mode, the MAX value can be rewritten in the procedure shown below even if the counter is running.

1. Check to see if the T16B $n$ CTL.MAXBSY bit is set to 0.
2. Write the MAX value to the T16B $n$ MC.MC[15:0] bits.

### Counter reset

Setting the T16B $n$ CTL.PRESET bit to 1 resets the counter. This clears the counter to 0x0000 in up or up/down mode, or presets the MAX value to the counter in down mode.

The counter is also cleared to 0x0000 when the counter value exceeds the MAX value during count up operation.

### Counting start

To start counting, set the T16B $n$ CTL.RUN bit to 1. The counting stop control depends on the count mode set.

### Counter value read

The counter value can be read out from the T16B $n$ TC.TC[15:0] bits. However, since T16B operates on CLK\_ T16B $n$ , one of the operations shown below is required to read correctly by the CPU.

- Read the counter value twice or more and check to see if the same value is read.
- Stop the timer and then read the counter value.

### Counter status check

The counter operating status can be checked using the T16B $n$ CS.BSY bit. The T16B $n$ CS.BSY bit is set to 1 while the counter is running or 0 while the counter is idle.

The current count direction can also be checked using the T16B $n$ CS.UP\_DOWN bit. The T16B $n$ CS.UP\_DOWN bit is set to 1 during count up operation or 0 during count down operation.

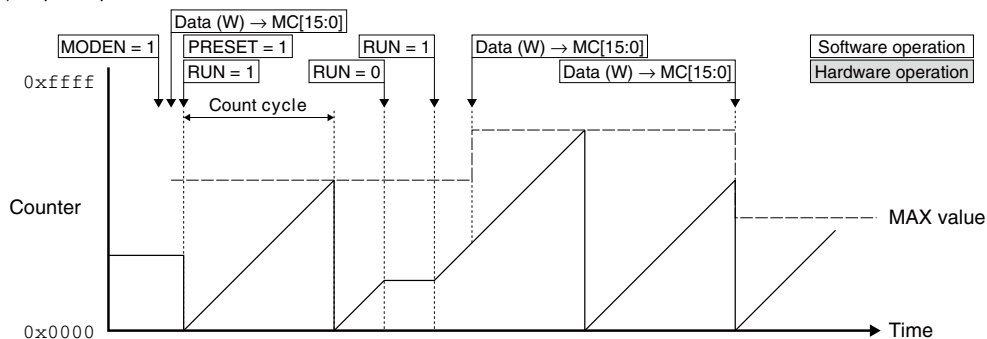

### Operations in repeat up count and one-shot up count modes

In these modes, the counter operates as an up counter and counts from 0x0000 (or current value) to the MAX value.

In repeat up count mode, the counter returns to 0x0000 if it exceeds the MAX value and continues counting until the T16B $n$ CTL.RUN bit is set to 0. If the MAX value is altered to a value larger than the current counter value during counting, the counter keeps counting up to the new MAX value. If the MAX value is altered to a value smaller than the current counter value, the counter is cleared to 0x0000 and continues counting up to the new MAX value.

In one-shot up count mode, the counter returns to 0x0000 if it exceeds the MAX value and stops automatically at that point.

(1) Repeat up count mode

(2) One-shot up count mode

Figure 15.4.2.1 Operations in Repeat Up Count and One-shot Up Count Modes

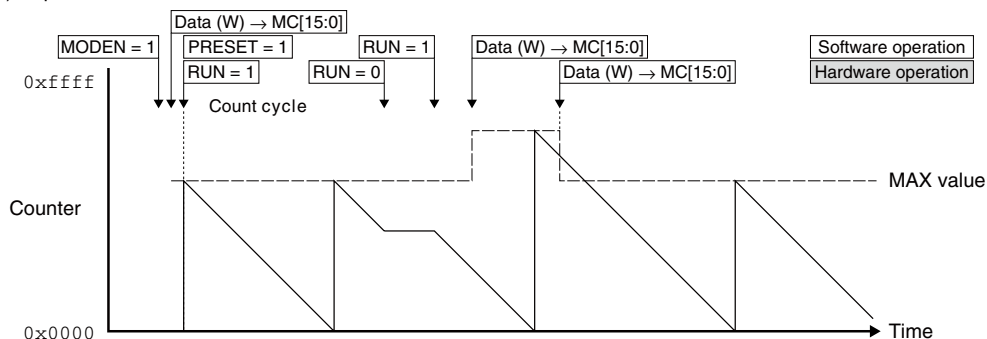

### Operations in repeat down count and one-shot down count modes

In these modes, the counter operates as a down counter and counts from the MAX value (or current value) to 0x0000.

In repeat down count mode, the counter returns to the MAX value if a counter underflow occurs and continues counting until the T16BnCTL.RUN bit is set to 0. If the MAX value is altered during counting, the counter keeps counting down to 0x0000 and continues counting down from the new MAX value after a counter underflow occurs.

In one-shot down count mode, the counter returns to the MAX value if a counter underflow occurs and stops automatically at that point.

(1) Repeat down count mode

## (2) One-shot down count mode

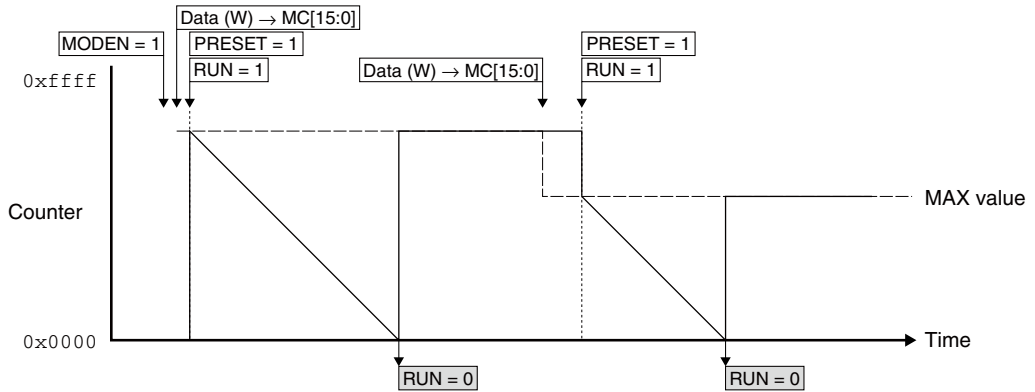

Figure 15.4.2.2 Operations in Repeat Down Count and One-shot Down Count Modes

**Operations in repeat up/down count and one-shot up/down count modes**

In these modes, the counter operates as an up/down counter and counts as 0x0000 (or current value) → the MAX value → 0x0000.

In repeat up/down count mode, the counter repeats counting up from 0x0000 to the MAX value and counting down from the MAX value to 0x0000 until the T16BnCTL.RUN bit is set to 0. If the MAX value is altered to a value larger than the current counter value during count up operation, the counter keeps counting up to the new MAX value. If the MAX value is altered to a value smaller than the current counter value, the counter is cleared to 0x0000 and continues counting up to the new MAX value. If the MAX value is altered during count down operation, the counter keeps counting down to 0x0000 and then starts counting up to the new MAX value.

In one-shot up/down count mode, the counter stops automatically when it reaches 0x0000 during count down operation.

### 15.4.3 Comparator/Capture Block Operations

The comparator/capture block functions as a comparator to compare the counter value with the register value set or a capture circuit to capture counter values using the external/software trigger signals.

#### Comparator/capture block operating mode

The comparator/capture block includes two systems (four or six systems) of comparator/capture circuits and each system can be set to comparator mode or capture mode, individually.

Set the T16BnCCCTLm.CCMD bit to 0 to set the comparator/capture circuit *m* to comparator mode or 1 to set it to capture mode.

#### Operations in comparator mode

The comparator mode compares the counter value and the value set via software. It generates an interrupt and toggles the timer output signal level when the values are matched. The T16BnCCRm register functions as the compare data register used for setting a comparison value in this mode. The TOUTnm/CAPnm pin is configured to the TOUTnm pin.

When the counter reaches the value set in the T16BnCCRm register during counting, the comparator asserts the MATCH signal and sets the T16BnINTF.COMPCAPmIF bit (compare interrupt flag) to 1.

When the counter reaches the MAX value in comparator mode, the T16BnINTF.CNTMAXIF bit (counter MAX interrupt flag) is set to 1. When the counter reaches 0x0000, the T16BnINTF.CNTZEROIF bit (counter zero interrupt flag) is set to 1.

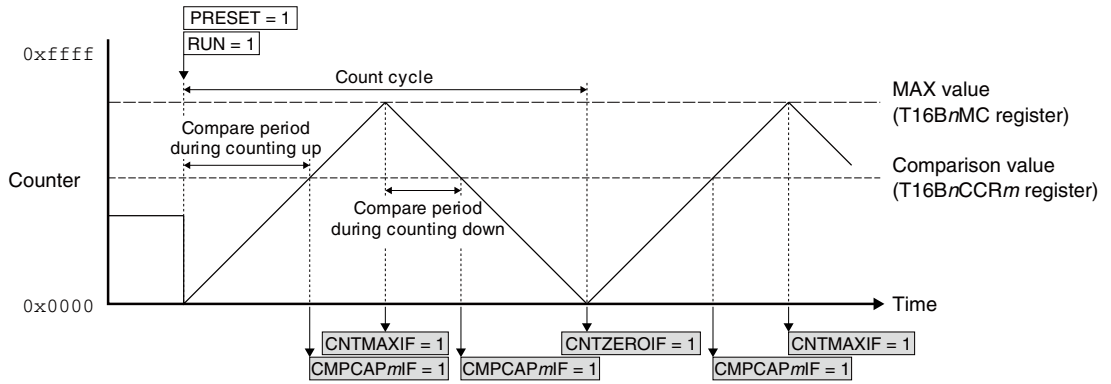

(1) Repeat up count mode

(2) Repeat down count mode

(3) Repeat up/down count mode

(Note that the T16BnINTF.CMPCAPmIF/CNTMAXIF/CNTZEROIF bit clearing operations via software are omitted from the figure.)

Figure 15.4.3.1 Operation Examples in Comparator Mode

The time from counter = 0x0000 or MAX value to occurrence of a compare interrupt (compare period) and the time to occurrence of a counter MAX or counter zero interrupt (count cycle) can be calculated as follows:

During counting up

$$\text{Compare period} = \frac{(CC + 1)}{f_{CLK\_T16B}} [s] \quad \text{Count cycle} = \frac{(MAX + 1)}{f_{CLK\_T16B}} [s] \quad (\text{Eq. 15.1})$$

During counting down

$$\text{Compare period} = \frac{(MAX - CC + 1)}{f_{CLK\_T16B}} [s] \quad \text{Count cycle} = \frac{(MAX + 1)}{f_{CLK\_T16B}} [s] \quad (\text{Eq. 15.2})$$

Where

CC: T16BnCCRm register setting value (0 to 65,535)

MAX: T16BnMC register setting value (0 to 65,535)

fCLK\_T16B: Count clock frequency [Hz]

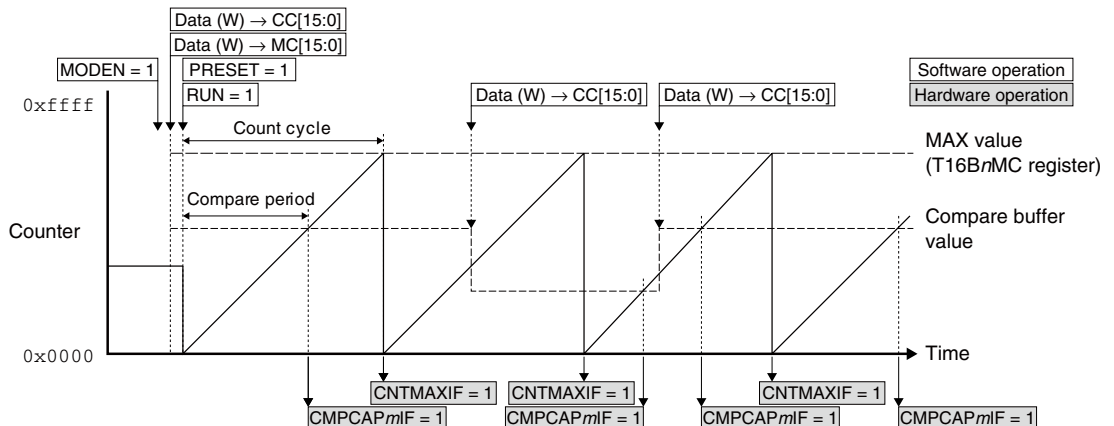

The comparator MATCH signal and counter MAX/ZERO signals are also used to generate a timer output waveform (TOUT). Refer to “TOUT Output Control” for more information.

**Compare buffer**

The comparator loads the comparison value, which has been written to the T16BnCCRm register, to the compare buffer before comparing it with the counter value. For example, when generating a PWM waveform, the waveform with the desired duty ratio may not be generated if the comparison value is altered asynchronous to the count operation. To avoid this problem, the timing to load the comparison value to the compare buffer can be configured using the T16BnCCCTLm.CBUFMD[2:0] bits for synchronization with the count operation.

(1) Repeat up count mode

(1.1) T16BnCCCTLm.CBUFMD[2:0] bits = 0x0

## 15 16-BIT PWM TIMERS (T16B)

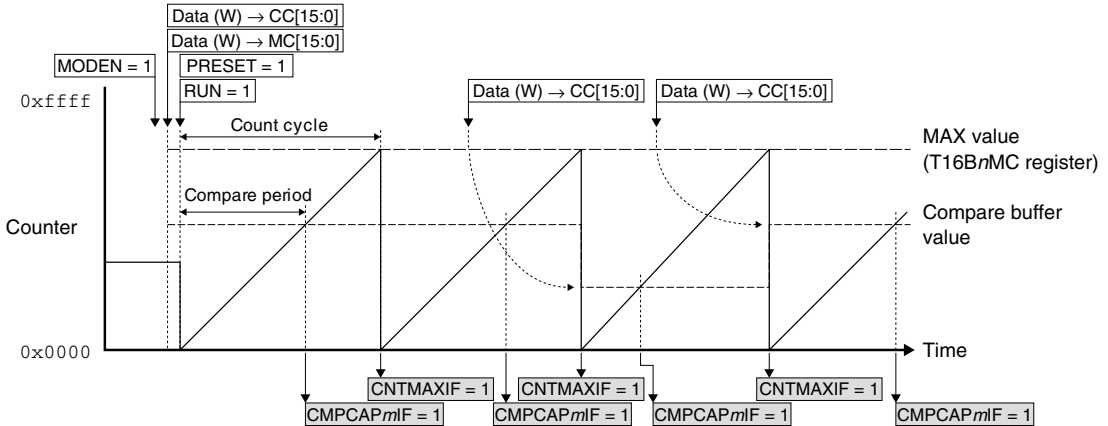

(1.2) T16BnCCCTLm.CBUFMD[2:0] bits = 0x1

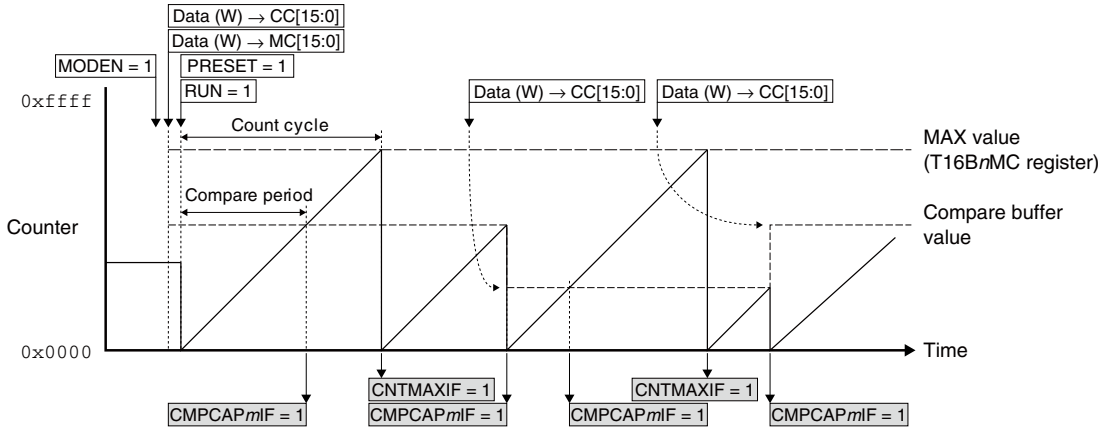

(1.3) T16BnCCCTLm.CBUFMD[2:0] bits = 0x2

(1.4) T16BnCCCTLm.CBUFMD[2:0] bits = 0x3

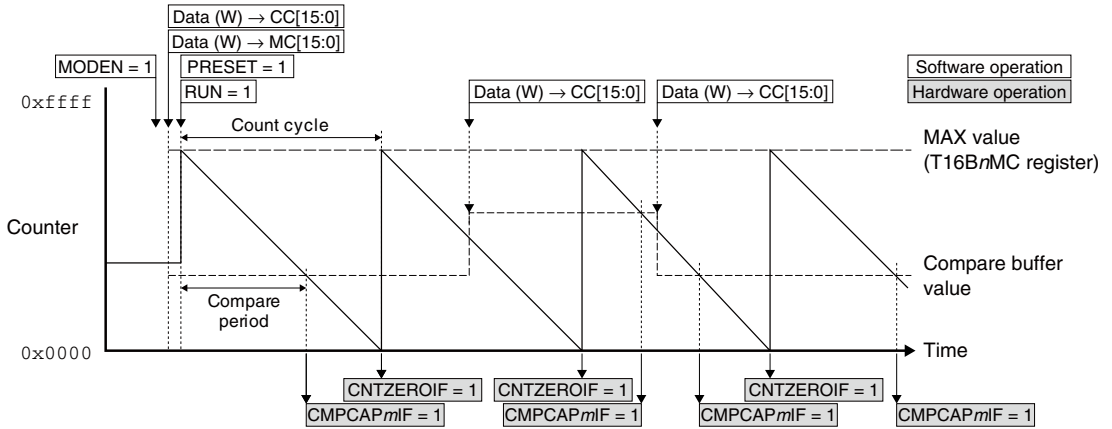

(1.5) T16BnCCCTLm.CBUFMD[2:0] bits = 0x4

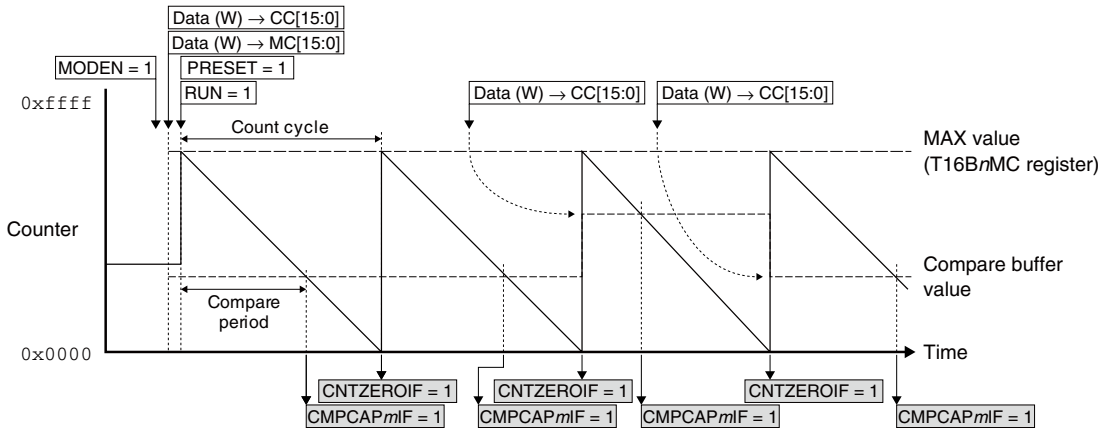

(2) Repeat down count mode

(2.1) T16BnCCCTLm.CBUFMD[2:0] bits = 0x0

(2.2) T16BnCCCTLm.CBUFMD[2:0] bits = 0x1

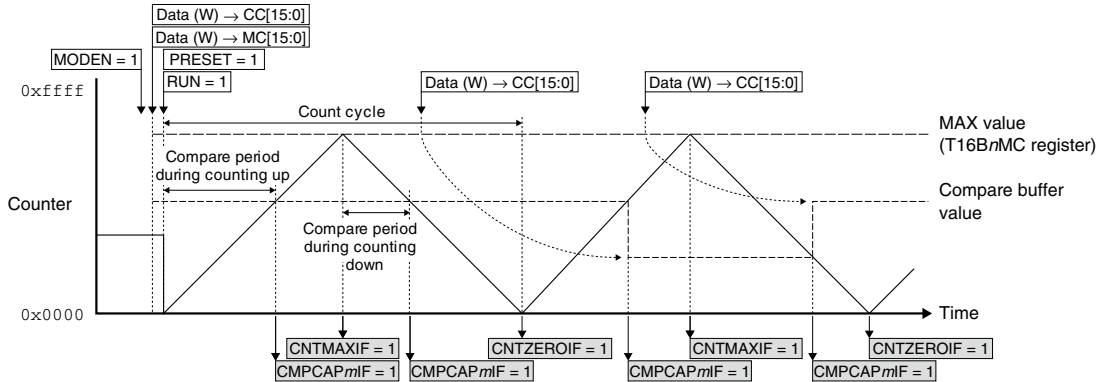

(3) Repeat up/down count mode  
 (3.1) T16BnCCCTLm.CBUFMD[2:0] bits = 0x0

(3.2) T16BnCCCTLm.CBUFMD[2:0] bits = 0x1

(3.3) T16BnCCCTLm.CBUFMD[2:0] bits = 0x2

An overwrite error occurs as the T16BnINTF.CMPCAPmIF bit has not been cleared.

Figure 15.4.3.3 Operations in Capture Mode (Example in One-shot Up Count Mode)

**Synchronous capture mode/asynchronous capture mode**

The capture circuit can operate in two operating modes: synchronous capture mode and asynchronous capture mode.

Synchronous capture mode is provided to avoid the possibility of invalid data reading by capturing counter data simultaneously with the counter being counted up/down. Set the T16BnCCCTLm.SCS bit to 1 to set the capture circuit to synchronous capture mode. This mode captures counter data by synchronizing the capture signal with the counter clock.

On the other hand, asynchronous capture mode can capture counter data by detecting a trigger pulse even if the pulse is shorter than the counter clock cycle that becomes invalid in synchronous capture mode. Set the T16BnCCCTLm.SCS bit to 0 to set the capture circuit to asynchronous capture mode.

(1) Synchronous capture mode

(2) Asynchronous capture mode

Figure 15.4.3.4 Synchronous Capture Mode/Asynchronous Capture Mode

### 15.4.4 TOUT Output Control

Comparator mode can generate TOUT signals using the comparator MATCH and counter MAX/ZERO signals. The generated signals can be output to outside the IC. Figure 15.4.4.1 shows the TOUT output circuits (circuits 0 and 1).

Figure 15.4.4.1 TOUT Output Circuits (Circuits 0 and 1)

Each timer channel includes two (four, or six) TOUT output circuits and their signal generation and output can be controlled individually.

#### TOUT generation mode

The  $T16BnCCCTLm.TOUTMD[2:0]$  bits are used to set how the TOUT signal waveform is changed by the MATCH and MAX/ZERO signals.

Furthermore, when the  $T16BnCCCTLm.TOUTMT$  bit is set to 1, the TOUT circuit uses the MATCH signal output from another system in the circuit pair (0 and 1, 2 and 3, 4 and 5). This makes it possible to change the signal twice within a counter cycle.

#### TOUT signal polarity

The TOUT signal polarity (active level) can be set using the  $T16BnCCCTLm.TOUTINV$  bit. It is set to active high by setting the  $T16BnCCCTLm.TOUTINV$  bit to 0 and active low by setting to 1.

Figures 15.4.4.2 and 15.4.4.3 show the TOUT output waveforms.

## 15.5 Interrupt

Each T16B channel has a function to generate the interrupt shown in Table 15.5.1.

Table 15.5.1 T16B Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Capture overwrite	T16BnINTF.CAPOWmIF	When the T16BnINTF.CMPCAPmIF bit =1 and the T16BnCCRm register is overwritten with new captured data in capture mode	Writing 1
Compare/capture	T16BnINTF.CMPCAPmIF	When the counter value becomes equal to the compare buffer value in comparator mode When the counter value is loaded to the T16BnCCRm register by a capture trigger input in capture mode	Writing 1
Counter MAX	T16BnINTF.CNTMAXIF	When the counter reaches the MAX value	Writing 1
Counter zero	T16BnINTF.CNTZEROIF	When the counter reaches 0x0000	Writing 1

T16B provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## T16B Ch. $n$ Counter Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16B $n$ CTL	15–9	–	0x00	–	R	–
	8	MAXBSY	0	H0	R	
	7–6	–	0x0	–	R	
	5–4	CNTMD[1:0]	0x0	H0	R/W	
	3	ONEST	0	H0	R/W	
	2	RUN	0	H0	R/W	
	1	PRESET	0	H0	R/W	
	0	MODEN	0	H0	R/W	

### Bits 15–9 Reserved

#### Bit 8 MAXBSY

This bit indicates whether data can be written to the T16B $n$ MC register or not.

1 (R): Busy status (cannot be written)

0 (R): Idle (can be written)

While this bit is 1, the T16B $n$ MC register is loading the MAX value. Data writing is prohibited during this period.

### Bits 7–6 Reserved

#### Bits 5–4 CNTMD[1:0]

These bits select the counter up/down mode. The count mode is configured with this selection and the T16B $n$ CTL.ONEST bit setting (see Table 15.6.2).

#### Bit 3 ONEST

This bit selects the counter repeat/one-shot mode. The count mode is configured with this selection and the T16B $n$ CTL.CNTMD[1:0] bit settings (see Table 15.6.2).

Table 15.6.2 Count Mode

T16BnCTL.CNTMD[1:0] bits	Count mode	
	T16BnCTL.ONEST bit = 1	T16BnCTL.ONEST bit = 0
0x3	Reserved	
0x2	One-shot up/down count mode	Repeat up/down count mode
0x1	One-shot down count mode	Repeat down count mode
0x0	One-shot up count mode	Repeat up count mode

**Bit 2 RUN**

This bit starts/stops counting.

1 (W): Start counting

0 (W): Stop counting

1 (R): Counting

0 (R): Idle

By writing 1 to this bit, the counter block starts count operations. However, the T16BnCTL.MODEN bit must be set to 1 in conjunction with this bit or it must be set in advance. While the timer is running, writing 0 to the T16BnCTL.RUN bit stops count operations. When the counter stops by the counter MAX/ZERO signal in one-shot mode, this bit is automatically cleared to 0.

**Bit 1 PRESET**

This bit resets the counter.

1 (W): Reset

0 (W): Ineffective

1 (R): Resetting in progress

0 (R): Resetting finished or normal operation

In up mode or up/down mode, the counter is cleared to 0x0000 by writing 1 to this bit. In down mode, the MAX value, which has been set to the T16BnMC register, is preset to the counter. However, the T16BnCTL.MODEN bit must be set to 1 in conjunction with this bit or it must be set in advance.

**Bit 0 MODEN**

This bit enables the T16B Ch.n operations.

1 (R/W): Enable (Start supplying operating clock)

0 (R/W): Disable (Stop supplying operating clock)

**Note:** The counter reset operation using the T16BnCTL.PRESET bit and the counting start operation using the T16BnCTL.RUN bit take effect only when the T16BnCTL.MODEN bit = 1.

**T16B Ch.n Max Counter Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16BnMC	15-0	MC[15:0]	0xffff	H0	R/W	-

**Bits 15-0 MC[15:0]**

These bits are used to set the MAX value to preset to the counter. For more information, refer to "Counter Block Operations - MAX counter data register."

- Notes:**
- When one-shot mode is selected, do not alter the T16BnMC.MC[15:0] bits (MAX value) during counting.
  - Make sure the T16BnCTL.MODEN bit is set to 1 before writing data to the T16BnMC.MC[15:0] bits. If the T16BnCTL.MODEN bit = 0 when writing to the T16BnMC.MC[15:0] bits, set the T16BnCTL.MODEN bit to 1 until the T16BnCS.BSY bit is set to 0 from 1.
  - Do not set the T16BnMC.MC[15:0] bits to 0x0000.

**T16B Ch.n Timer Counter Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
T16BnTC	15-0	TC[15:0]	0x0000	H0	R	-

**Bits 15–0 TC[15:0]**

The current counter value can be read out through these bits.

### Bit 15 SCS

This bit selects either synchronous capture mode or asynchronous capture mode.

1 (R/W): Synchronous capture mode

0 (R/W): Asynchronous capture mode

For more information, refer to “Comparator/Capture Block Operations - Synchronous capture mode/asynchronous capture mode.” The T16BnCCCTL*m*.SCS bit is control bit for capture mode and is ineffective in comparator mode.

### Bits 14–12 CBUFMD[2:0]

These bits select the timing to load the comparison value written in the T16BnCCR*m* register to the compare buffer. The T16BnCCCTL*m*.CBUFMD[2:0] bits are control bits for comparator mode and are ineffective in capture mode.

### Bits 11–10 CAPIS[1:0]

These bits select the trigger signal for capturing (see Table 15.6.4). The T16BnCCCTL*m*.CAPIS[1:0] bits are control bits for capture mode and are ineffective in comparator mode.

### Bits 9–8 CAPTRG[1:0]

These bits select the trigger edge(s) of the trigger signal at which the counter value is captured in the T16BnCCR*m* register in capture mode (see Table 15.6.4). The T16BnCCCTL*m*.CAPTRG[1:0] bits are control bits for capture mode and are ineffective in comparator mode.

0x0	Not triggered (disable capture function)	

**Bit 7**      **Reserved**

**Bit 6**      **TOUTMT**

This bit selects whether the comparator MATCH signal of another system is used for generating the TOUTnm signal or not.

1 (R/W): Generate TOUT using two comparator MATCH signals of the comparator circuit pair (0 and 1, 2 and 3, 4 and 5)

0 (R/W): Generate TOUT using one comparator MATCH signal of comparator *m* and the counter MAX or ZERO signals

The T16BnCCCTLm.TOUTMT bit is control bit for comparator mode and is ineffective in capture mode.

**Bit 5**      **TOUTO**

This bit sets the TOUTnm signal output level when software control mode (T16BnCCCTLm.TOUTMD[2:0] = 0x0) is selected for the TOUTnm output.

1 (R/W): High level output

0 (R/W): Low level output

The T16BnCCCTLm.TOUTO bit is control bit for comparator mode and is ineffective in capture mode.

**Bits 4–2**    **TOUTMD[2:0]**

These bits configure how the TOUTnm signal waveform is changed by the comparator MATCH and counter MAX/ZERO signals.

The T16BnCCCTLm.TOUTMD[2:0] bits are control bits for comparator mode and are ineffective in capture mode.

This bit selects the TOUTnm signal polarity.

1 (R/W): Inverted (active low)

0 (R/W): Normal (active high)

The T16BnCCCTLm.TOUTINV bit is control bit for comparator mode and is ineffective in capture mode.

**Bit 0 CCMD**

This bit selects the operating mode of the comparator/capture circuit m.

1 (R/W): Capture mode (T16nCCRm register = capture register)

0 (R/W): Comparator mode (T16nCCRm register = compare data register)

**Bits 15-0 CC[15:0]**

In comparator mode, this register is configured as the compare data register and used to set the comparison value to be compared with the counter value.

In capture mode, this register is configured as the capture register and the counter value captured by the capture trigger signal is loaded.

# 16 Sound Generator (SNDA)

## 16.1 Overview

SNDA is a sound generator that generates melodies and buzzer signals. The features of the SNDA are listed below.

- Sound output mode is selectable from three types.
  1. Normal buzzer mode (for normal buzzer output of which the output duration is controlled via software)
    - Output frequency: Can be set within the range of 512 Hz to 16,384 Hz.
    - Duty ratio: Can be set within the range of 0 % to 100 %.
  2. One-shot buzzer mode (for short buzzer output such as a clicking sound)
    - Output frequency: Can be set within the range of 512 Hz to 16,384 Hz.
    - Duty ratio: Can be set within the range of 0 % to 100 %.
    - One-shot output duration: Can be set within the range of 15.6 ms to 250 ms. (16 types)
  3. Melody mode (for playing single note melody)
    - Pitch: Can be set within the range of 128 Hz to 16,384 Hz.  
(Scale: 3 octave from C3 to C6 with reference to A4 = 443 Hz)
    - Duration: Can be set within the range of half note/rest to thirty-second note/rest. (7 types)
    - Tempo: Can be set within the range of 30 to 480. (16 types)
    - Other: Tie and slur can be specified.
- A piezoelectric buzzer can be driven with the inverted and non-inverted output pins.
- Can control the non-inverted output pin status while sound stops.

Figure 16.1.1 shows the SNDA configuration.

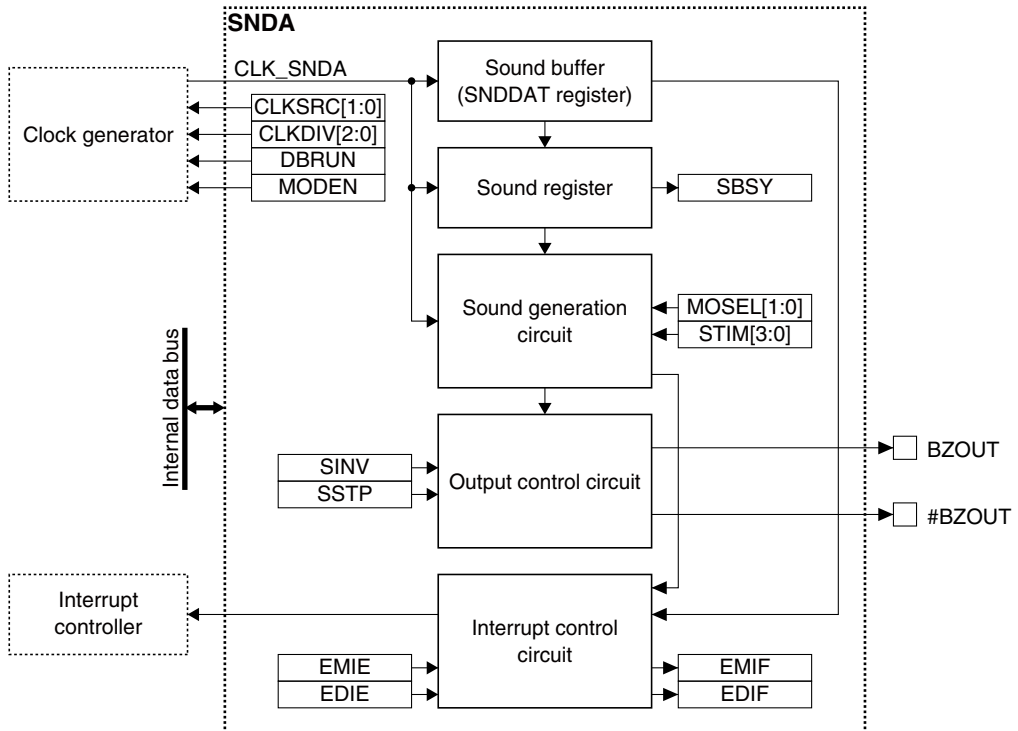

Figure 16.1.1 SNDA Configuration

## 16.2 Output Pins and External Connections

### 16.2.1 List of Output Pins

Table 16.2.1.1 lists the SNDA pins.

Table 16.2.1.1 List of SNDA Pins

Pin name	I/O*	Initial status*	Function
BZOUT	O	O (Low)	Non-inverted buzzer output pin
#BZOUT	O	O (Low)	Inverted buzzer output pin

\* Indicates the status when the pin is configured for SNDA

If the port is shared with the SNDA pin and other functions, the SNDA output function must be assigned to the port before activating the SNDA. For more information, refer to the “I/O Ports” chapter.

### 16.2.2 Output Pin Drive Mode

The drive mode of the BZOUT and #BZOUT pins can be set to one of the two types shown below using the SNDSEL.SINV bit.

#### Direct drive mode (SNDSEL.SINV bit = 0)

This mode drives both the BZOUT and #BZOUT pins to low while the buzzer signal output is off to prevent the piezoelectric buzzer from applying unnecessary bias.

#### Normal drive mode (SNDSEL.SINV bit = 1)

In this mode, the #BZOUT pin always outputs the inverted signal of the BZOUT pin even when the buzzer output is off.

### 16.2.3 External Connections

Figures 16.2.2.1 and 16.2.2.2 show connection diagrams between SNDA and a piezoelectric buzzer.

Figure 16.2.2.1 Connection between SNDA and Piezoelectric Buzzer (Direct Drive)

Figure 16.2.2.2 Connection between SNDA and Piezoelectric Buzzer (Single Pin Drive)

## 16.3 Clock Settings

---

### 16.3.1 SNDA Operating Clock

When using SNDA, the SNDA operating clock CLK\_SNDA must be supplied to SNDA from the clock generator. The CLK\_SNDA supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following SNDCLK register bits:
  - SNDCLK.CLKSRC[1:0] bits (Clock source selection)
  - SNDCLK.CLKDIV[2:0] bits (Clock division ratio selection = Clock frequency setting)

The CLK\_SNDA frequency should be set to around 32,768 Hz.

### 16.3.2 Clock Supply in SLEEP Mode

When using SNDA during SLEEP mode, the SNDA operating clock CLK\_SNDA must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_SNDA clock source.

If the CLGOSC.xxxxSLPC bit for the CLK\_SNDA clock source is 1, the CLK\_SNDA clock source is deactivated during SLEEP mode and SNDA stops with the register settings maintained at those before entering SLEEP mode. After the CPU returns to normal mode, CLK\_SNDA is supplied and the SNDA operation resumes.

### 16.3.3 Clock Supply in DEBUG Mode

The CLK\_SNDA supply during DEBUG mode should be controlled using the SNDCLK.DBRUN bit.

The CLK\_SNDA supply to SNDA is suspended when the CPU enters DEBUG mode if the SNDCLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_SNDA supply resumes. Although SNDA stops operating when the CLK\_SNDA supply is suspended, the output pin and registers retain the status before DEBUG mode was entered. If the SNDCLK.DBRUN bit = 1, the CLK\_SNDA supply is not suspended and SNDA will keep operating in DEBUG mode.

## 16.4 Operations

---

### 16.4.1 Initialization

SNDA should be initialized with the procedure shown below.

1. Assign the SNDA output function to the ports. (Refer to the “I/O Ports” chapter.)
2. Configure the SNDA operating clock.
3. Set the SNDCTL.MODEN bit to 1. (Enable SNDA operations)
4. Set the SNDSEL.SINV bit. (Set output pin drive mode)
5. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the SNDINTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the SNDINTE register to 1. (Enable interrupts)

### 16.4.2 Buzzer Output in Normal Buzzer Mode

Normal buzzer mode generates a buzzer signal with the software specified frequency and duty ratio, and outputs the generated signal to outside the IC. The buzzer output duration can also be controlled via software.

An output start/stop procedure and the SNDA operations are shown below.

#### Normal buzzer output start/stop procedure

1. Set the SNDSEL.MOSEL[1:0] bits to 0x0. (Set normal buzzer mode)

2. Write data to the following sound buffer (SNDDAT register) bits. (Start buzzer output)
  - SNDDAT.SLEN[5:0] bits (Set buzzer output signal duty ratio)
  - SNDDAT.SFRQ[7:0] bits (Set buzzer output signal frequency)
3. Write 1 to the SNDCTL.SSTP bit after the output period has elapsed. (Stop buzzer output)

### Normal buzzer output operations

When data is written to the sound buffer (SNDDAT register), SNDA clears the SNDINTF.EMIF bit (sound buffer empty interrupt flag) to 0 and starts buzzer output operations.

The data written to the sound buffer is loaded into the sound register in sync with the CLK\_SNDA clock. At the same time, the SNDINTF.EMIF bit and SNDINTF.SBSY bit are both set to 1. The output pin outputs the buzzer signal with the frequency/duty ratio specified.

Writing 1 to the SNDCTL.SSTP bit stops buzzer output and sets the SNDINTF.EDIF bit (sound output completion interrupt flag) to 1. The SNDINTF.SBSY bit is cleared to 0.

Figure 16.4.2.1 shows a buzzer output timing chart in normal buzzer mode.

Figure 16.4.2.1 Buzzer Output Timing Chart in Normal Buzzer Mode

### Buzzer output waveform configuration (normal buzzer mode/one-shot buzzer mode)

Set the buzzer signal frequency and duty ratio (high period/cycle) using the SNDDAT.SFRQ[7:0] and SNDDAT.SLEN[5:0] bits, respectively. Use the following equations to calculate these setting values.

$$\text{SNDDAT.SFRQ}[7:0] \text{ bits} = \frac{f_{\text{CLK\_SNDA}}}{f_{\text{BZOUT}}} - 1 \quad (\text{Eq. 16.1})$$

$$\text{SNDDAT.SLEN}[5:0] \text{ bits} = \left( \frac{f_{\text{CLK\_SNDA}}}{f_{\text{BZOUT}}} \times \frac{\text{DUTY}}{100} \right) - 1 \quad (\text{Eq. 16.2})$$

Where

- f<sub>CLK\_SNDA</sub>: CLK\_SNDA frequency [Hz]
- f<sub>BZOUT</sub>: Buzzer signal frequency [Hz]
- DUTY: Buzzer signal duty ratio [%]

However, the following settings are prohibited:

- Settings as SNDDAT.SFRQ[7:0] bits ≤ SNDDAT.SLEN[5:0] bits
- Settings as SNDDAT.SFRQ[7:0] bits = 0x00

### 16.4.3 Buzzer Output in One-shot Buzzer Mode

One-shot buzzer mode is provided for clicking sound and short-duration buzzer output. This mode generates a buzzer signal with the software specified frequency and duty ratio, and outputs the generated signal for the short duration specified.

An output start procedure and the SNDA operations are shown below. For the buzzer output waveform, refer to “Buzzer Output in Normal Buzzer Mode.”

#### One-shot buzzer output start procedure

- Set the following SNDSEL register bits:
  - Set the SNDSEL.MOSEL[1:0] bits to 0x1. (Set one-shot buzzer mode)
  - SNDSEL.STIM[3:0] bits (Set output duration)
- Write data to the following sound buffer (SNDDAT register) bits. (Start buzzer output)
  - SNDDAT.SLEN[5:0] bits (Set buzzer output signal duty ratio)
  - SNDDAT.SFRQ[7:0] bits (Set buzzer output signal frequency)

#### One-shot buzzer output operations

When data is written to the sound buffer (SNDDAT register), SNDA clears the SNDINTF.EMIF bit (sound buffer empty interrupt flag) to 0 and starts buzzer output operations.

The data written to the sound buffer is loaded into the sound register in sync with the CLK\_SNDA clock. At the same time, the SNDINTF.EMIF bit and SNDINTF.SBSY bit are both set to 1. The output pin outputs the buzzer signal with the frequency/duty ratio specified.

The buzzer output automatically stops when the duration specified by the SNDSEL.STIM[3:0] bits has elapsed. At the same time, the SNDINTF.EDIF bit (sound output completion interrupt flag) is set to 1 and the SNDINTF.SBSY bit is cleared to 0.

Figure 16.4.3.1 shows a buzzer output timing chart in one-shot buzzer mode.

Figure 16.4.3.1 Buzzer Output Timing Chart in One-shot Buzzer Mode

## 16.4.4 Output in Melody Mode

Melody mode generates the buzzer signal with a melody according to the data written to the sound buffer (SNDDAT register) successively, and outputs the generated signal to outside the IC. An output start procedure and the SNDA operations are shown below.

### Melody output start procedure

- Set the following SNDSSEL register bits:
  - Set the SNDSSEL.MOSEL[1:0] bits to 0x2. (Set melody mode)
  - SNDSSEL.STIM[3:0] bits (Set tempo)
- Write data to the following sound buffer (SNDDAT register) bits. (Start sound output)
  - SNDDAT.MDTI bit (Set tie/slur)
  - SNDDAT.MDRS bit (Set note/rest)
  - SNDDAT.SLEN[5:0] bits (Set duration)
  - SNDDAT.SFRQ[7:0] bits (Set scale)
- Check to see if the SNDINTF.EMIF bit is set to 1 (an interrupt can be used).
- Repeat Steps 2 and 3 until the end of the melody.

### Melody output operations

When data is written to the sound buffer (SNDDAT register), SNDA clears the SNDINTF.EMIF bit (sound buffer empty interrupt flag) to 0 and starts sound output operations.

The data written to the sound buffer is loaded into the sound register by the internal trigger signal. At the same time, the SNDINTF.EMIF bit and SNDINTF.SBSY bit are both set to 1. The output pin outputs the sound specified.

The sound output stops if data is not written to the sound buffer (SNDDAT register) until the next trigger is issued. At the same time, the SNDINTF.EDIF bit (sound output completion interrupt flag) is set to 1 and the SNDINTF.SBSY bit is cleared to 0.

Figure 16.4.4.1 shows a melody mode operation timing chart.

### Melody output waveform configuration

#### Note/rest (duration) specification

Notes and rests can be specified using the SNDDAT.MDRS and SNDDAT.SLEN[5:0] bits.

Table 16.4.4.1 Note/Rest Specification (when  $f_{CLK\_SNDA} = 32,768$  Hz)

SNDDAT.SLEN[5:0] bits	SNDDAT.MDRS bit	
	0: Note	1: Rest

0x03	Eighth note	Eighth rest
0x01	Sixteenth note	Sixteenth rest
0x00	Thirty-second note	Thirty-second rest
Other	Setting prohibited	

#### Tie/slur specification

A tie or slur takes effect by setting the SNDDAT.MDTI bit to 1 and the previous note and the current note are played continuously.

Figure 16.4.4.2 Tie and Slur

#### Scale specification

Scales can be specified using the SNDDAT.SFRQ[7:0] bits.

## 16.5 Interrupts

SNDA has a function to generate the interrupts shown in Table 16.5.1.

Table 16.5.1 SNDA Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Sound buffer empty	SNDINTF.EMIF	When data in the sound buffer (SNDDAT register) is transferred to the sound register or 1 is written to the SNDCTL.SSTP bit	Writing to the SNDDAT register
Sound output completion	SNDINTF.EDIF	When a sound output has completed	Writing 1 or writing to the SNDDAT register

SNDA provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 16.6 Control Registers

### SNDA Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDCLK	15–9	–	0x00	–	R	–
	8	DBRUN	0	H0	R/W	
	7	–	0	–	R	
	6–4	CLKDIV[2:0]	0x0	H0	R/W	
	3–2	–	0x0	–	R	
	1–0	CLKSRC[1:0]	0x0	H0	R/W	

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the SNDA operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

**Bit 7 Reserved**

## 16 SOUND GENERATOR (SNDA)

### Bits 6–4 CLKDIV[2:0]

These bits select the division ratio of the SNDA operating clock.

### Bits 3–2 Reserved

### Bits 1–0 CLKSRC[1:0]

These bits select the clock source of SNDA.

Table 16.6.1 Clock Source and Division Ratio Settings

SNDCLK. CLKDIV[2:0] bits	SNDCLK.CLKSRC[1:0] bits			
	0x0	0x1	0x2	0x3
	IOSC	OSC1	OSC3	EXOSC
0x7	Reserved	1/1	Reserved	1/1
0x6				
0x5	1/128		1/128	
0x4	1/64		1/64	
0x3	1/32		1/32	
0x2	1/16		1/16	
0x1	1/8		1/8	
0x0	1/4		1/4	

(Note) The oscillation circuits/external input that are not supported in this IC cannot be selected as the clock source.

**Note:** The SNDCLK register settings can be altered only when the SNDCTL.MODEN bit = 0.

## SNDA Select Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDSEL	15–12	–	0x0	–	R	–
	11–8	STIM[3:0]	0x0	H0	R/W	
	7–3	–	0x00	–	R	
	2	SINV	0	H0	R/W	
	1–0	MOSEL[1:0]	0x0	H0	R/W	

### Bits 15–12 Reserved

### Bits 11–8 STIM[3:0]

These bits select a tempo (when melody mode is selected) or a one-shot buzzer output duration (when one-shot buzzer mode is selected).

Table 16.6.2 Tempo/One-shot Buzzer Output Duration Selections (when  $f_{CLK\_SNDA} = 32,768$  Hz)

SNDSEL. STIM[3:0] bits	Tempo (= Quarter note/minute)	One-shot buzzer output duration [ms]
0xf	30	250.0
0xe	32	234.4
0xd	34.3	218.8
0xc	36.9	203.1
0xb	40	187.5
0xa	43.6	171.9
0x9	48	156.3
0x8	53.3	140.6
0x7	60	125.0
0x6	68.6	109.4
0x5	80	93.8
0x4	96	78.1
0x3	120	62.5
0x2	160	46.9
0x1	240	31.3
0x0	480	15.6

**Note:** Be sure to avoid altering these bits when SNDINTF.SBSY bit = 1.

### Bits 7–3 Reserved

**Bit 2 SINV**

This bit selects an output pin drive mode.

1 (R/W): Normal drive mode

0 (R/W): Direct drive mode

For more information, refer to “Output Pin Drive Mode.”

**Bits 1–0 MOSEL[1:0]**

These bits select a sound output mode.

Table 16.6.3 Sound Output Mode Selection

SNDSEL.MOSEL[1:0] bits	Sound output mode
0x3	Reserved
0x2	Melody mode
0x1	One-shot buzzer mode
0x0	Normal buzzer mode

**SNDA Control Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDCTL	15–9	–	0x00	–	R	–
	8	SSTP	0	H0	R/W	
	7–1	–	0x00	–	R	
	0	MODEN	0	H0	R/W	

**Bits 15–9 Reserved****Bit 8 SSTP**

This bit stops sound output.

1 (W): Stop sound output

0 (W): Ineffective

1 (R): In stop process

0 (R): Stop process completed/Idle

The SNDCTL.SSTP bit is used to stop buzzer output in normal buzzer mode. After 1 is written, this bit is cleared to 0 when the sound output has completed. Also in one-shot buzzer mode/melody mode, writing 1 to this bit can forcibly terminate the sound output.

**Bits 7–1 Reserved****Bit 0 MODEN**

This bit enables the SNDA operations.

1 (R/W): Enable SNDA operations (The operating clock is supplied.)

0 (R/W): Disable SNDA operations (The operating clock is stopped.)

**SNDA Data Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDDAT	15	MDTI	0	H0	R/W	–
	14	MDRS	0	H0	R/W	
	13–8	SLEN[5:0]	0x00	H0	R/W	
	7–0	SFRQ[7:0]	0xff	H0	R/W	

This register functions as a sound buffer. Writing data to this register starts sound output. For detailed information on the setting data, refer to “Buzzer output waveform configuration (normal buzzer mode/one-shot buzzer mode)” and “Melody output waveform configuration.”

**Bit 15 MDTI**

This bit specifies a tie or slur (continuous play with the previous note) in melody mode.

1 (R/W): Enable tie/slur

0 (R/W): Disable tie/slur

This bit is ignored in normal buzzer mode/one-shot buzzer mode.

## 16 SOUND GENERATOR (SNDA)

### Bit 14 MDRS

This bit selects the output type in melody mode from a note or a rest .

1 (R/W): Rest

0 (R/W): Note

When a rest is selected, the BZOUT pin goes low and the #BZOUT pin goes high during the output duration. This bit is ignored in normal buzzer mode/one-shot buzzer mode.

### Bits 13–8 SLEN[5:0]

These bits select a duration (when melody mode is selected) or a buzzer signal duty ratio (when normal buzzer mode/one-shot buzzer mode is selected).

### Bits 7–0 SFRQ[7:0]

These bits select a scale (when melody mode is selected) or a buzzer signal frequency (when normal buzzer mode/one-shot buzzer mode is selected).

- Notes:**
- In normal buzzer mode/one-shot buzzer mode, only the low-order 6 bits (SNDDAT.SFRQ[5:0] bits) are effective within the SNDDAT.SFRQ[7:0] bits. Always set the SNDDAT.SFRQ[7:6] bits to 0x0.
  - The SNDDAT register allows 16-bit data writing only. Data writings in 8-bit size will be ignored.

## SNDA Interrupt Flag Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDINTF	15–9	–	0x00	–	R	–
	8	SBSY	0	H0	R	
	7–2	–	0x00	–	R	
	1	EMIF	1	H0	R	Cleared by writing to the SNDDAT register.
	0	EDIF	0	H0	R/W	Cleared by writing 1 or writing to the SNDDAT register.

### Bits 15–9 Reserved

### Bit 8 SBSY

This bit indicates the sound output status. (See Figures 16.4.2.1, 16.4.3.1, and 16.4.4.1.)

1 (R): Outputting

0 (R): Idle

### Bits 7–2 Reserved

### Bit 1 EMIF

### Bit 0 EDIF

These bits indicate the SNDA interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

The following shows the correspondence between the bit and interrupt:

SNDINTF.EMIF bit: Sound buffer empty interrupt

SNDINTF.EDIF bit: Sound output completion interrupt

## SNDA Interrupt Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
SNDINTE	15-8	-	0x00	-	R	-
	7-2	-	0x00	-	R	
	1	EMIE	0	H0	R/W	
	0	EDIE	0	H0	R/W	

### Bits 15-2 Reserved

**Bit 1**      **EMIE**

**Bit 0**      **EDIE**

These bits enable SNDA interrupts.

1 (R/W): Enable interrupts

0 (R/W): Disable interrupts

The following shows the correspondence between the bit and interrupt:

SNDINTE.EMIE bit: Sound buffer empty interrupt

SNDINTE.EDIE bit: Sound output completion interrupt

# 17 IR Remote Controller (REMC2)

## 17.1 Overview

The REMC2 circuit generates infrared remote control output signals. This circuit can also be applicable to an EL lamp drive circuit by adding a simple external circuit.

The features of the REMC2 are listed below.

- Outputs an infrared remote control signal.
- Includes a carrier generator.
- Flexible carrier signal generation and data pulse width modulation.
- Automatic data setting function for continuous data transmission.
- Output signal inverting function supporting various formats.
- EL lamp drive waveform can be generated for an application example.

Figure 17.1.1 shows the REMC2 configuration.

Table 17.1.1 REMC2 Channel Configuration of S1C17W03/W04

Item	32-pin package	48-pin package/chip
Number of channels	1 transmitter channel	

Figure 17.1.1 REMC2 Configuration

## 17.2 Input/Output Pins and External Connections

### 17.2.1 Output Pin

Table 17.2.1.1 shows the REMC2 pin.

Table 17.2.1.1 REMC2 Pin

Pin name	I/O*	Initial status*	Function
REMO	O	O (L)	IR remote controller transmit data output
CLPLS	O	O (L)	IR remote controller clear pulse output

\* Indicates the status when the pin is configured for the REMC2.

## 17 IR REMOTE CONTROLLER (REMC2)

If the port is shared with the REMC2 pin and other functions, the REMC2 output function must be assigned to the port before activating the REMC2. For more information, refer to the “I/O Ports” chapter.

### 17.2.2 External Connections

Figure 17.2.2.1 shows a connection example between the REMC2 and an external infrared module.

Figure 17.2.2.1 Connection Example Between REMC2 and External Infrared Module

## 17.3 Clock Settings

### 17.3.1 REMC2 Operating Clock

When using the REMC2, the REMC2 operating clock CLK\_REMC2 must be supplied to the REMC2 from the clock generator. The CLK\_REMC2 supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following REMCLK register bits:
  - REMCLK.CLKSRC[1:0] bits (Clock source selection)
  - REMCLK.CLKDIV[3:0] bits (Clock division ratio selection = Clock frequency setting)

### 17.3.2 Clock Supply in SLEEP Mode

When using REMC2 during SLEEP mode, the REMC2 operating clock CLK\_REMC2 must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the CLK\_REMC2 clock source.

If the CLGOSC.xxxxSLPC bit for the CLK\_REMC2 clock source is 1, the CLK\_REMC2 clock source is deactivated during SLEEP mode and REMC2 stops with the register settings maintained at those before entering SLEEP mode. After the CPU returns to normal mode, CLK\_REMC2 is supplied and the REMC2 operation resumes.

### 17.3.3 Clock Supply in DEBUG Mode

The CLK\_REMC2 supply during DEBUG mode should be controlled using the REMCLK.DBRUN bit.

The CLK\_REMC2 supply to the REMC2 is suspended when the CPU enters DEBUG mode if the REMCLK.DBRUN bit = 0. After the CPU returns to normal mode, the CLK\_REMC2 supply resumes. Although the REMC2 stops operating when the CLK\_REMC2 supply is suspended, the output pin and registers retain the status before DEBUG mode was entered. If the REMCLK.DBRUN bit = 1, the CLK\_REMC2 supply is not suspended and the REMC2 will keep operating in DEBUG mode.

## 17.4 Operations

### 17.4.1 Initialization

The REMC2 should be initialized with the procedure shown below.

1. Write 1 to the REMDBCTL.REMCRST bit. (Reset REMC2)
2. Configure the REMCLK.CLKSRC[1:0] and REMCLK.CLKDIV[3:0] bits. (Configure operating clock)
3. Assign the REMC2 output function to the port. (Refer to the “I/O Ports” chapter.)

4. Configure the following REMDBCTL register bits:
  - Set the REMDBCTL.MODEN bit to 1. (Enable count operation clock)
  - REMDBCTL.TRMD bit (Select repeat mode/one-shot mode)
  - Set the REMDBCTL.BUFEN bit to 1. (Enable compare buffer)
  - REMDBCTL.REMOINV bit (Configure inverse logic output signal)
5. Configure the following REMCARR register bits:
  - REMCARR.CRPER[7:0] bit (Set carrier signal cycle)
  - REMCARR.CRDTY[7:0] bit (Set carrier signal duty)
6. Set the REMCCTL.CARREN bit. (Enable/disable carrier modulation)
7. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the REMINTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the REMINTE register to 1. (Enable interrupts)

## 17.4.2 Data Transmission Procedures

### Starting data transmission

The following shows a procedure to start data transmission.

1. Set the REMAPLEN.APLEN[15:0] bits. (Set data signal duty)
2. Set the REMDBLEN.DBLEN[15:0] bits. (Set data signal cycle)
3. Set the following REMDBCTL register bits:
  - Set the REMDBCTL.PRESET bit to 1. (Reset internal counters)
  - Set the REMDBCTL.PRUN bit to 1. (Start counting)

### Continuous data transmission control

The following shows a procedure to send data continuously after starting data transmission (after Step 3 above).

1. Set the duty and cycle for the subsequent data to the REMAPLEN.APLEN[15:0] and REMDBLEN.DBLEN[15:0] bits, respectively, before a compare DB interrupt (REMINTF.DBIF bit = 1) occurs. (It is not necessary to rewrite settings when sending the same data with the current settings.)
2. Wait for a compare DB interrupt (REMINTF.DBIF bit = 1).
3. Repeat Steps 1 and 2 until the end of data.

### Terminating data transmission

The following shows a procedure to terminate data transmission.

1. Wait for a compare DB interrupt (REMINTF.DBIF bit = 1).
2. Set the REMDBCTL.PRUN bit to 0. (Stop counting)
3. Set the REMDBCTL.MODEN bit to 0. (Disable count operation clock)

## 17.4.3 REMO Output Waveform

Carrier refers to infrared frequency in infrared remote control communication. Note, however, that carrier in this manual refers to sub-carrier used in infrared remote control communication, as REMC2 does not control infrared rays directly.

The REMC2 outputs the logical AND between the carrier signal output from the carrier generator and the data signal output from the data signal generator. Figure 17.4.3.1 shows an example of the output waveform.

Figure 17.4.3.1 REMO Output Waveform Example

### Carrier signal

The carrier signal is generated by comparing the values of the 8-bit counter for carrier generation that runs with CLK\_REMC2 and the setting values of the REMCARR.CRDTY[7:0] and REMCARR.CRPER[7:0] bits. Figure 17.4.3.2 shows an example of the carrier signal generated.

Example) REMCARR.CRDTY[7:0] bits = 2, REMCARR.CRPER[7:0] bits = 8

A: REMCARR.CRDTY[7:0] bits + 1 [clock]  
 B: REMCARR.CRPER[7:0] bits + 1 [clock]

Figure 17.4.3.2 Example of Carrier Signal Generated

The carrier signal frequency and duty ratio can be calculated by the equations shown below.

$$\text{Carrier frequency} = \frac{f_{\text{CLK\_REMC2}}}{\text{CRPER} + 1} \quad \text{Duty ratio} = \frac{\text{CRDTY} + 1}{\text{CRPER} + 1} \quad (\text{Eq. 17.1})$$

Where

- f<sub>CLK\_REMC2</sub>: CLK\_REMC2 frequency [Hz]
- CRPER: REMCARR.CRPER[7:0] bit-setting value (1–255)
- CRDTY: REMCARR.CRDTY[7:0] bit-setting value (0–254)
- \* REMCARR.CRDTY[7:0] bits < REMCARR.CRPER[7:0] bits

The 8-bit counter for carrier generation is reset by the REMDBCTL.PRESET bit and is started/stopped by the REMDBCTL.PRUN bit in conjunction with the 16-bit counter for data signal generation. When the counter value is matched with the REMCARR.CRDTY[7:0] bits, the carrier signal waveform is inverted. When the counter value is matched with the REMCARR.CRPER[7:0] bits, the carrier signal waveform is inverted and the counter is reset to 0x00.

### Data signal

The data signal is generated by comparing the values of the 16-bit counter for data signal generation (REMDBCTL.DBCNT[15:0] bits) that runs with CLK\_REMC2 and the setting values of the REMAPLEN.APLEN[15:0] and REMDBLEN.DBLEN[15:0] bits. Figure 17.4.3.3 shows an example of the data signal generated.

Example) REMAPLEN.APLEN[15:0] bits = 0x0bd0, REMDBLEN.DBLEN[15:0] bits = 0x11b8,  
 REMDBCTL.TRMD bit = 0 (repeat mode), REMDBCTL.REMOINV bit = 0 (signal logic non-inverted)

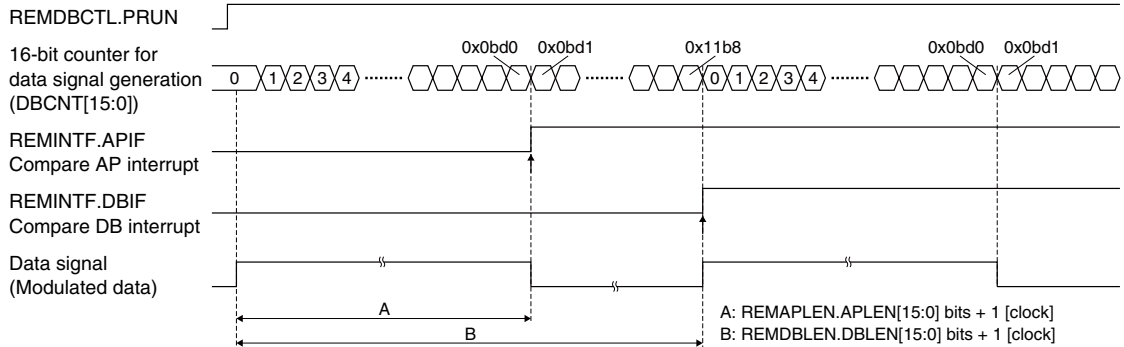

Figure 17.4.3.3 Example of Data Signal Generated

The data length and duty ratio of the pulse-width-modulated data signal can be calculated with the equations shown below.

$$\text{Data length} = \frac{\text{DBLEN} + 1}{f_{\text{CLK\_REMC2}}} \quad \text{Duty ratio} = \frac{\text{APLEN} + 1}{\text{DBLEN} + 1} \quad (\text{Eq. 17.2})$$

Where

- f<sub>CLK\_REMC2</sub>: CLK\_REMC2 frequency [Hz]
- DBLEN: REMDBLEN.DBLEN[15:0] bit-setting value (1–65,535)
- APLEN: REMAPLEN.APLEN[15:0] bit-setting value (0–65,534)
- \* REMAPLEN.APLEN[15:0] bits < REMDBLEN.DBLEN[15:0] bits

The 16-bit counter for data signal generation is reset by the REMDBCTL.PRESET bit and is started/stopped by the REMDBCTL.PRUN bit. When the counter value is matched with the REMAPLEN.APLEN[15:0] bits (compare AP), the data signal waveform is inverted. When the counter value is matched with the REMDBLEN.DBLEN[15:0] bits (compare DB), the data signal waveform is inverted and the counter is reset to 0x0000.

A different interrupt can be generated when the counter value is matched with the REMDBLEN.DBLEN[15:0] and REMAPLEN.APLEN[15:0] bits, respectively.

### Repeat mode and one-shot mode

When the 16-bit counter for data signal generation is set to repeat mode (REMDBCTL.TRMD bit = 0), the counter keeps operating until it is stopped using the REMDBCTL.PRUN bit. When the counter is set to one-shot mode (REMDBCTL.TRMD bit = 1), the counter stops automatically when the counter value is matched with the REMDBLEN.DBLEN[15:0] bit-setting value.

## 17.4.4 Continuous Data Transmission and Compare Buffers

Figure 17.4.4.1 shows an operation example of continuous data transmission with the compare buffer enabled.

## 17 IR REMOTE CONTROLLER (REMC2)

Example) REMDBCTL.TRMD bit = 0 (repeat mode), REMDBCTL.BUFEN bit = 1 (compare buffer enabled), REMDBCTL.REMOINV bit = 0 (signal logic non-inverted)

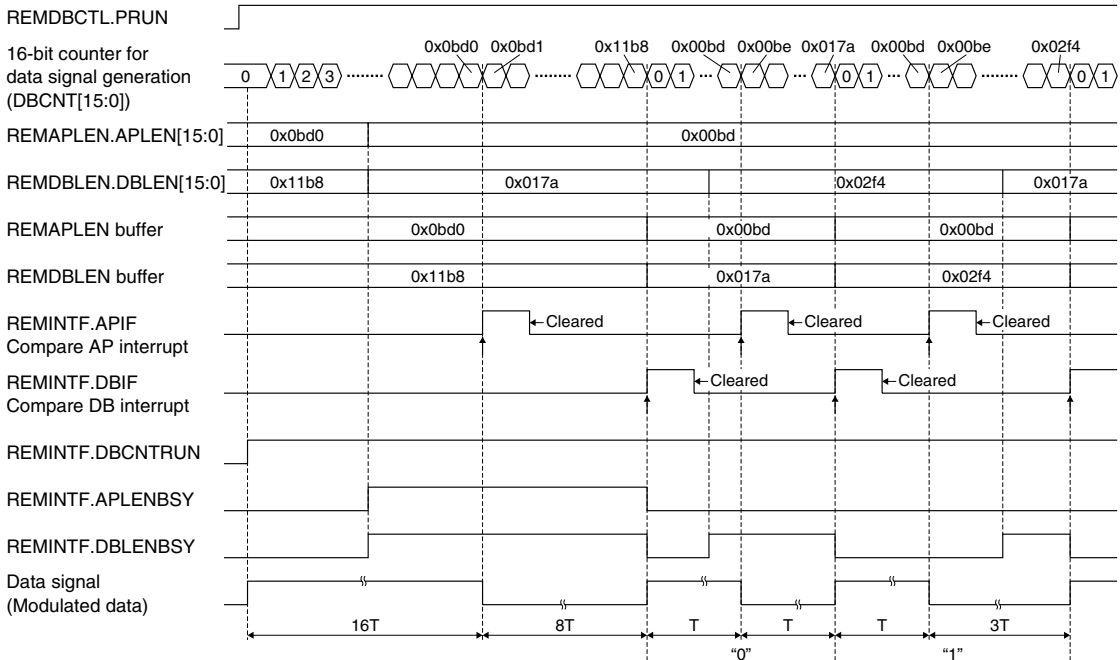

Figure 17.4.4.1 Continuous Data Transmission Example

When the compare buffer is disabled (REMDBCTL.BUFEN bit = 0), the 16-bit counter value is directly compared with the REMAPLEN.APLEN[15:0] and REMDBLEN.DBLEN[15:0] bit values. The comparison value is altered immediately after the REMAPLEN.APLEN[15:0] or REMDBLEN.DBLEN[15:0] bits are rewritten.

When the compare buffer is enabled (REMDBCTL.BUFEN bit = 1), the REMAPLEN.APLEN[15:0] and REMDBLEN.DBLEN[15:0] bit values are loaded into the compare buffers provided respectively (REMAPLEN buffer and REMDBLEN buffer) and the 16-bit counter value is compared with the compare buffers.

The comparison values are loaded into the compare buffers when the 16-bit counter is matched with the REMDBLEN buffer (when the count for the data length has completed). Therefore, the next transmit data can be set during the current data transmission. When the compare buffers are enabled, the buffer status flags (REMINTF.APLENBSY bit and REMINTF.DBLENBSY bit) become effective. The flag is set to 1 when the setting value is written to the register and cleared to 0 when the written value is transferred to the buffer.

## 17.5 Interrupts

The REMC2 has a function to generate the interrupts shown in Table 17.5.1.

Table 17.5.1 REMC2 Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Compare AP	REMINTF.APIF	When the REMAPLEN register (or REMAPLEN buffer) value and the 16-bit counter for data signal generation are matched	Writing 1 to the interrupt flag or the REMDBCTL.REMCRST bit
Compare DB	REMINTF.DBIF	When the REMDBLEN register (or REMDBLEN buffer) value and the 16-bit counter for data signal generation are matched	Writing 1 to the interrupt flag or the REMDBCTL.REMCRST bit

The REMC2 provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 17.6 Application Example: Driving EL Lamp

The REMC2 can be used to simply drive an EL lamp as an application example. Figures 17.6.1 and 17.6.2 show an example of an EL lamp drive circuit and an example of the drive waveform generated, respectively. For details of settings and an example of components, refer to the Application Note provided separately.

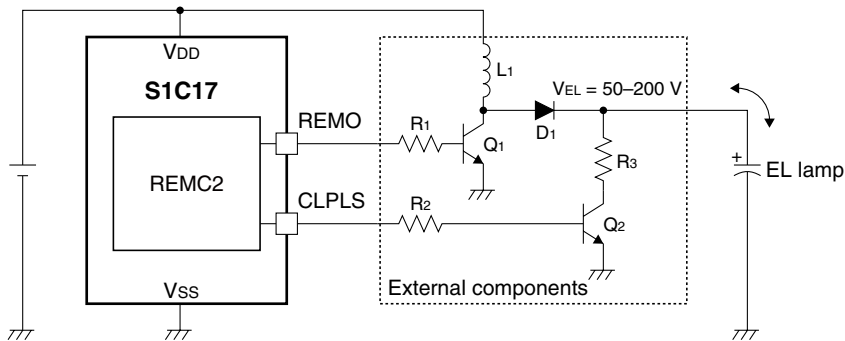

Figure 17.6.1 Example of EL Lamp Drive Circuit

Figure 17.6.2 Example of Generated Drive Waveform

The REMO and CLPLS signals are output from the respective pins while the REMDBCTL.PRUN bit = 1. The difference between the setting values of the REMDBLEN.DBLEN[15:0] bits and REMAPLEN.APLEN[15:0] bits becomes the CLPLS pulse width (high period).

## 17.7 Control Registers

### REMC2 Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMCLK	15-9	-	0x00	-	R	-
	8	DBRUN	0	H0	R/W	
	7-4	CLKDIV[3:0]	0x0	H0	R/W	
	3-2	-	0x0	-	R	
	1-0	CLKSRC[1:0]	0x0	H0	R/W	

**Bits 15-9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the REMC2 operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

**Bits 7-4 CLKDIV[3:0]**

These bits select the division ratio of the REMC2 operating clock.

**Bits 3-2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of the REMC2.

Table 17.7.1 Clock Source and Division Ratio Settings

REMCLK. CLKDIV[3:0] bits	REMCLK.CLKSRC[1:0] bits			
	0x0	0x1	0x2	0x3

0x0	1/1	1/1	1/1	

(Note) The oscillation circuits/external input that are not supported in this IC cannot be selected as the clock source.

**Note:** The REMCLK register settings can be altered only when the REMDBCTL.MODEN bit = 0.

**REMC2 Data Bit Counter Control Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMDBCTL	15–10	–	0x00	–	R	–
	9	PRESET	0	H0/S0	R/W	Cleared by writing 1 to the REMDBCTL.REMCRST bit.
	8	PRUN	0	H0/S0	R/W	
	7–5	–	0x0	–	R	–
	4	REMOINV	0	H0	R/W	
	3	BUFEN	0	H0	R/W	
	2	TRMD	0	H0	R/W	
	1	REMCRST	0	H0	W	
	0	MODEN	0	H0	R/W	

**Bits 15–10 Reserved****Bit 9 PRESET**

This bit resets the internal counters (16-bit counter for data signal generation and 8-bit counter for carrier generation).

1 (W): Reset

0 (W): Ineffective

1 (R): Resetting in progress

0 (R): Resetting finished or normal operation

Before the counter can be reset using this bit, the REMDBCTL.MODEN bit must be set to 1.

This bit is cleared to 0 after the counter reset operation has finished or when 1 is written to the REMDBCTL.REMCRST bit.

**Bit 8 PRUN**

This bit starts/stops counting by the internal counters (16-bit counter for data signal generation and 8-bit counter for carrier generation).

1 (W): Start counting

0 (W): Stop counting

1 (R): Counting

0 (R): Idle

Before the counter can start counting by this bit, the REMDBCTL.MODEN bit must be set to 1. While the counter is running, writing 0 to the REMDBCTL.PRUN bit stops count operations. When the counter stops by occurrence of a compare DB in one-shot mode, this bit is automatically cleared to 0.

**Bits 7–5 Reserved**

**Bit 4 REMOINV**

This bit inverts the REMO output signal.

1 (R/W): Inverted

0 (R/W): Non-inverted

For more information, see Figure 17.4.3.1.

**Bit 3 BUFEN**

This bit enables or disables the compare buffers.

1 (R/W): Enable

0 (R/W): Disable

For more information, refer to “Continuous Data Transmission and Compare Buffers.”

**Note:** The REMDBCTL.BUFEN bit must be set to 0 when setting the data signal duty and cycle for the first time.

**Bit 2 TRMD**

This bit selects the operation mode of the 16-bit counter for data signal generation.

1 (R/W): One-shot mode

0 (R/W): Repeat mode

For more information, refer to “REMO Output Waveform, Data signal.”

**Bit 1 REMCRST**

This bit issues software reset to the REMC2.

1 (W): Issue software reset

0 (W): Ineffective

1 (R): Software reset is executing.

0 (R): Software reset has finished. (During normal operation)

Setting this bit resets the REMC2 internal counters and interrupt flags. This bit is automatically cleared after the reset processing has finished.

**Note:** After the data signal is output in one-shot mode, set the REMDBCTL.REMCRST bit to 1.

**Bit 0 MODEN**

This bit enables the REMC2 operations.

1 (R/W): Enable REMC2 operations (The operating clock is supplied.)

0 (R/W): Disable REMC2 operations (The operating clock is stopped.)

**Note:** If the REMDBCTL.MODEN bit is altered from 1 to 0 while sending data, the data being sent cannot be guaranteed. When setting the REMDBCTL.MODEN bit to 1 again after that, be sure to write 1 to the REMDBCTL.REMCRST bit as well.

## REMC2 Data Bit Counter Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMCBCNT	15–0	DBCNT[15:0]	0x0000	H0/S0	R	Cleared by writing 1 to the REMDBCTL.REMCRST bit.

**Bits 15–0 DBCNT[15:0]**

The current value of the 16-bit counter for data signal generation can be read out through these bits.

## REMC2 Data Bit Active Pulse Length Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMAPLEN	15-0	APLEN[15:0]	0x0000	H0	R/W	Writing enabled when REMDBCTL.MODEN bit = 1.

### Bits 15-0 APLEN[15:0]

These bits set the active pulse length of the data signal (high period when the REMDBCTL.REMOINV bit = 0 or low period when the REMDBCTL.REMOINV bit = 1).

The REMO pin output is set to the active level from the 16-bit counter for data signal generation = 0x0000 and it is inverted to the inactive level when the counter exceeds the REMAPLEN.APLEN[15:0] bit-setting value. The data signal duty ratio is determined by this setting and the REMDBLEN.DBLEN[15:0] bit-setting. (See Figure 17.4.3.3.)

Before this register can be rewritten, the REMDBCTL.MODEN bit must be set to 1.

## REMC2 Data Bit Length Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMDBLEN	15-0	DBLEN[15:0]	0x0000	H0	R/W	Writing enabled when REMDBCTL.MODEN bit = 1.

### Bits 15-0 DBLEN[15:0]

These bits set the data length of the data signal (length of one cycle).

A data signal cycle begins with the 16-bit counter for data signal generation = 0x0000 and ends when the counter exceeds the REMDBLEN.DBLEN[15:0] bit-setting value. (See Figure 17.4.3.3.)

Before this register can be rewritten, the REMDBCTL.MODEN bit must be set to 1.

## REMC2 Status and Interrupt Flag Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMINTF	15-11	–	0x00	–	R	–
	10	DBCNTRUN	0	H0/S0	R	Cleared by writing 1 to the REMDBCTL.REMCRST bit.
	9	DBLENBSY	0	H0	R	Effective when the REMDBCTL.BUFEN bit = 1.
	8	APLENBSY	0	H0	R	Effective when the REMDBCTL.BUFEN bit = 1.
	7-2	–	0x00	–	R	–
	1	DBIF	0	H0/S0	R/W	Cleared by writing 1 to this bit or the REMDBCTL.REMCRST bit.
	0	APIF	0	H0/S0	R/W	

### Bits 15-11 Reserved

#### Bit 10 DBCNTRUN

This bit indicates whether the 16-bit counter for data signal generation is running or not. (See Figure 17.4.4.1.)

1 (R): Running (Counting)

0 (R): Idle

#### Bit 9 DBLENBSY

This bit indicates whether the value written to the REMDBLEN.DBLEN[15:0] bits is transferred to the REMDBLEN buffer or not. (See Figure 17.4.4.1.)

1 (R): Transfer to the REMDBLEN buffer has not completed.

0 (R): Transfer to the REMDBLEN buffer has completed.

While this bit is set to 1, writing to the REMDBLEN.DBLEN[15:0] bits is ineffective.

#### Bit 8 APLENBSY

This bit indicates whether the value written to the REMAPLEN.APLEN[15:0] bits is transferred to the REMAPLEN buffer or not. (See Figure 17.4.4.1.)

1 (R): Transfer to the REMAPLEN buffer has not completed.

0 (R): Transfer to the REMAPLEN buffer has completed.

While this bit is set to 1, writing to the REMAPLEN.APLEN[15:0] bits is ineffective.

**Bits 7–2 Reserved**

**Bit 1 DBIF**

**Bit 0 APIF**

These bits indicate the REMC2 interrupt cause occurrence status.

1 (R): Cause of interrupt occurred

0 (R): No cause of interrupt occurred

1 (W): Clear flag

0 (W): Ineffective

The following shows the correspondence between the bit and interrupt:

REMINTF.DBIF bit: Compare DB interrupt

REMINTF.APIF bit: Compare AP interrupt

These interrupt flags are also cleared to 0 when 1 is written to the REMDBCTL.REMCRST bit.

## REMC2 Interrupt Enable Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMINTE	15–8	–	0x00	–	R	–
	7–2	–	0x00	–	R	
	1	DBIE	0	H0	R/W	
	0	APIE	0	H0	R/W	

**Bits 15–2 Reserved**

**Bit 1 DBIE**

**Bit 0 APIE**

These bits enable REMC2 interrupts.

1 (R/W): Enable interrupts

0 (R/W): Disable interrupts

The following shows the correspondence between the bit and interrupt:

REMINTE.DBIE bit: Compare DB interrupt

REMINTE.APIE bit: Compare AP interrupt

## REMC2 Carrier Waveform Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMCARR	15–8	CRDTY[7:0]	0x00	H0	R/W	–
	7–0	CRPER[7:0]	0x00	H0	R/W	

**Bits 15–8 CRDTY[7:0]**

These bits set the high level period of the carrier signal.

The carrier signal is set to high level from the 8-bit counter for carrier generation = 0x00 and it is inverted to low level when the counter exceeds the REMCARR.CRDTY[7:0] bit-setting value. The carrier signal duty ratio is determined by this setting and the REMCARR.CRPER[7:0] bit-setting. (See Figure 17.4.3.2.)

**Bits 7–0 CRPER[7:0]**

These bits set the carrier signal cycle.

A carrier signal cycle begins with the 8-bit counter for carrier generation = 0x00 and ends when the counter exceeds the REMCARR.CRPER[7:0] bit-setting value. (See Figure 17.4.3.2.)

**REMC2 Carrier Modulation Control Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
REMCCTL	15–8	–	0x00	–	R	–
	7–1	–	0x00	–	R	
	0	CARREN	0	H0	R/W	

**Bits 15–1 Reserved**

**Bit 0 CARREN**

This bit enables carrier modulation.

1 (R/W): Enable carrier modulation

0 (R/W): Disable carrier modulation (output data signal only)

**Note:** When carrier modulation is disabled, the REMDBCTL.REMOINV bit should be set to 0.

# 18 R/F Converter (RFC)

## 18.1 Overview

The RFC is a CR oscillation type A/D converter (R/F converter).

The features of the RFC are listed below.

- Converts the sensor resistance into a digital value by performing CR oscillation and counting the oscillation clock.
- Achieves high-precision measurement system with low errors by oscillating the reference resistor and the sensor in the same conditions to obtain the difference between them.
- Includes a 24-bit measurement counter to count the oscillation clocks.
- Includes a 24-bit time base counter to count the internal clock for equalizing the measurement time between the reference resistor and the sensor.
- Supports DC bias resistive sensors and AC bias resistive sensors.  
(A thermometer/hygrometer can be easily implemented by connecting a thermistor or a humidity sensor and a few passive elements (resistor and capacitor).)
- Allows measurement (counting) by inputting external clocks.
- Provides an output and continuous oscillation function for monitoring the oscillation frequency.
- Can generate reference oscillation completion, sensor (A and B) oscillation completion, measurement counter overflow error, and time base counter overflow error interrupts.

Figure 18.1.1 shows the RFC configuration.

Table 18.1.1 RFC Channel Configuration of S1C17W03/W04

Item	32-pin package	48-pin package/chip
Number of channels	1 channel (Ch.0)	2 channels (Ch.0 and Ch.1) * Ch.1 can only be used in DC oscillation mode for resistive sensor measurements.

## 18.2 Input/Output Pins and External Connections

### 18.2.1 List of Input/Output Pins

Table 18.2.1.1 lists the RFC pins.

Table 18.2.1.1 List of RFC Pins

Pin name	I/O*	Initial status*	Function
SENB $n$	A	Hi-Z	Sensor B oscillation control pin
SENA $n$	A	Hi-Z	Sensor A oscillation control pin
REF $n$	A	Hi-Z	Reference oscillation control pin
RFIN $n$	A	V <sub>ss</sub>	RFCLK input or oscillation control pin
RFCLKOn	O	Hi-Z	RFCLK monitoring output pin RFCLK is output to monitor the oscillation frequency.

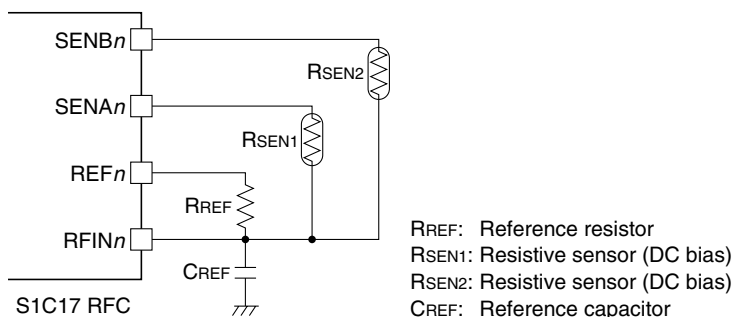

\* Indicates the status when the pin is configured for the RFC.

If the port is shared with the RFC pin and other functions, the RFC input/output function must be assigned to the port before activating the RFC. For more information, refer to the “I/O Ports” chapter.

**Note:** The RFIN $n$  pin goes to V<sub>ss</sub> level when the port is switched. Be aware that large current may flow if the pin is biased by an external circuit.

### 18.2.2 External Connections

The figures below show connection examples between the RFC and external sensors. For the oscillation mode and external clock input mode, refer to “Operating Mode.”

\* Leave the unused pin (SENA $n$  or SENB $n$ ) open if one resistive sensor only is used.

\* Leave the unused pins open.

Figure 18.2.2.3 External Clock Input in External Clock Input Mode

## 18.3 Clock Settings

### 18.3.1 RFC Operating Clock

When using the RFC, the RFC operating clock TCCLK must be supplied to the RFC from the clock generator. The TCCLK supply should be controlled as in the procedure shown below.

1. Enable the clock source in the clock generator if it is stopped (refer to “Clock Generator” in the “Power Supply, Reset, and Clocks” chapter).
2. Set the following RFC<sub>n</sub>CLK register bits:
  - RFC<sub>n</sub>CLK.CLKSRC[1:0] bits (Clock source selection)
  - RFC<sub>n</sub>CLK.CLKDIV[1:0] bits (Clock division ratio selection = Clock frequency setting)

The time base counter performs counting with TCCLK set here. Selecting a higher clock results in higher conversion accuracy, note, however, that the frequency should be determined so that the time base counter will not overflow during reference oscillation.

### 18.3.2 Clock Supply in SLEEP Mode

When using RFC during SLEEP mode, the RFC operating clock TCCLK must be configured so that it will keep supplying by writing 0 to the CLGOSC.xxxxSLPC bit for the TCCLK clock source.

### 18.3.3 Clock Supply in DEBUG Mode

The TCCLK supply during DEBUG mode should be controlled using the RFC<sub>n</sub>CLK.DBRUN bit.

The TCCLK supply to the RFC is suspended when the CPU enters DEBUG mode if the RFC<sub>n</sub>CLK.DBRUN bit = 0. After the CPU returns to normal mode, the TCCLK supply resumes. Although the RFC stops operating when the TCCLK supply is suspended, the output pin and registers retain the status before DEBUG mode was entered. If the RFC<sub>n</sub>CLK.DBRUN bit = 1, the TCCLK supply is not suspended and the RFC will keep operating in DEBUG mode.

## 18.4 Operations

### 18.4.1 Initialization

The RFC should be initialized with the procedure shown below.

1. Configure the RFC<sub>n</sub>CLK.CLKSRC[1:0] and RFC<sub>n</sub>CLK.CLKDIV[1:0] bits. (Configure operating clock)
2. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the RFC<sub>n</sub>INTF register. (Clear interrupt flags)
  - Set the interrupt enable bits in the RFC<sub>n</sub>INTE register to 1. (Enable interrupts)
3. Assign the RFC input/output function to the ports. (Refer to the “I/O Ports” chapter.)

## 18 R/F CONVERTER (RFC)

4. Configure the following RFC<sub>n</sub>CTL register bits:
  - RFC<sub>n</sub>CTL.EVTEN bit (Enable/disable external clock input mode)
  - RFC<sub>n</sub>CTL.SMODE[1:0] bits (Select oscillation mode)
  - Set the RFC<sub>n</sub>CTL.MODEN bit to 1. (Enable RFC operations)

### 18.4.2 Operating Modes

The RFC has two oscillation modes that use the RFC internal oscillation circuit and an external clock input mode for measurements using an external input clock. The channels may be configured to a different mode from others.

#### Oscillation mode

The oscillation mode is selected using the RFC<sub>n</sub>CTL.SMODE[1:0] bits.

##### DC oscillation mode for resistive sensor measurements

This mode performs measurements by DC driving the reference resistor and the resistive sensor to oscillate. Set the RFC into this mode when a DC bias resistive sensor is connected. This mode allows connection of two resistive sensors to a channel.

##### AC oscillation mode for resistive sensor measurements

This mode performs measurements by AC driving the reference resistor and the resistive sensor to oscillate. Set the RFC into this mode when an AC bias resistive sensor is connected. One resistive sensor only can be connected to a channel.

#### External clock input mode (event counter mode)

This mode enables input of external clock/pulses to perform counting similar to the internal oscillation clock. A sine wave may be input as well as a square wave (for the threshold value of the Schmitt input, refer to “R/F Converter Characteristics, High level Schmitt input threshold voltage  $V_{T+}$  and Low level Schmitt input threshold voltage  $V_{T-}$ ” in the “Electrical Characteristics” chapter). This function is enabled by setting the RFC<sub>n</sub>CTL.EVTEN bit to 1. The measurement procedure is the same as when the internal oscillation circuit is used.

### 18.4.3 RFC Counters

The RFC incorporates two counters shown below.

#### Measurement counter (MC)

The measurement counter is a 24-bit presettable up counter. Counting the reference oscillation clock and the sensor oscillation clock for the same duration of time using this counter minimizes errors caused by voltage, and unevenness of IC quality, as well as external parts and on-board parasitic elements. The counter values should be corrected via software after the reference and sensor oscillations are completed according to the sensor characteristics to determine the value being currently detected by the sensor.

#### Time base counter (TC)

The time base counter is a 24-bit presettable up/down counter. The time base counter counts up with TCCLK during reference oscillation to measure the reference oscillation time. During sensor oscillation, it counts down from the reference oscillation time and stops the sensor oscillation when it reaches 0x000000. This means that the sensor oscillation time becomes equal to the reference oscillation time. The value counted during reference oscillation should be saved in the memory. It can be reused at subsequent sensor oscillations omitting reference oscillations.

#### Counter initial value

To obtain the difference between the reference oscillation and sensor oscillation clock count values from the measurement counter simply, appropriate initial values must be set to the measurement counter before starting reference oscillation.

Connecting the reference element and sensor with the same resistance will result in <Initial value: n> = <Counter value at the end of sensor oscillation: m> (if error = 0). Setting a large <Initial value: n> increases the resolution of measurement. However, the measurement counter may overflow during sensor oscillation when the sensor value decreases below the reference element value (the measurement will be canceled). The initial value for the measurement counter should be determined taking the range of sensor value into consideration. The time base counter should be set to 0x000000 before starting reference oscillation.

### Counter value read

The measurement and time base counters operate on RFCCLK and TCCLK, respectively. Therefore, to read correctly by the CPU while the counter is running, read the counter value twice or more and check to see if the same value is read.

## 18.4.4 Converting Operations and Control Procedure

An R/F conversion procedure and the RFC operations are shown below. Although the following descriptions assume that the internal oscillation circuit is used, external clock input mode can be controlled with the same procedure.

### R/F control procedure

1. Set the initial value (0x000000 - n) to the RFCnMCH and RFCnMCL registers (measurement counter).
2. Clear the RFCnTCH and RFCnTCL registers (time base counter) to 0x000000.
3. Clear both the RFCnINTF.EREFIF and RFCnINTF.OVTCIF bits by writing 1.
4. Set the RFCnTRG.SREF bit to 1 to start reference oscillation.
5. Wait for an RFC interrupt.
  - i. If the RFCnINTF.EREFIF bit = 1 (reference oscillation completion), clear the RFCnINTF.EREFIF bit and then go to Step 6.
  - ii. If the RFCnINTF.OVTCIF bit = 1 (time base counter overflow error), clear the RFCnINTF.OVTCIF bit and terminate measurement as an error or retry after altering the measurement counter initial value.
6. Clear the RFCnINTF.ESENAIF, RFCnINTF.ESENBIF, and RFCnINTF.OVMCIF bits by writing 1.
7. Set the RFCnTRG.SSENA bit (sensor A) or the RFCnTRG.SSENB bit (sensor B) corresponding to the sensor to be measured to 1 to start sensor oscillation (use the RFCnTRG.SSENA bit in AC oscillation mode).
8. Wait for an RFC interrupt.
  - i. If the RFCnINTF.ESENAIF bit = 1 (sensor A oscillation completion) or the RFCnINTF.ESENBIF bit = 1 (sensor B oscillation completion), clear the RFCnINTF.ESENAIF or RFCnINTF.ESENBIF bit and then go to Step 9.
  - ii. If the RFCnINTF.OVMCIF bit = 1 (measurement counter overflow error), clear the RFCnINTF.OVMCIF bit and terminate measurement as an error or retry after altering the measurement counter initial value.
9. Read the RFCnMCH and RFCnMCL registers (measurement counter) and correct the results depending on the sensor to obtain the detected value.

### R/F converting operations

#### Reference oscillation

When the RFCnTRG.SREF bit is set to 1 in Step 4 of the conversion procedure above, the RFC Ch.n starts CR oscillation using the reference resistor. The measurement counter starts counting up using the CR oscillation clock from the initial value that has been set. The time base counter starts counting up using TCCLK from 0x000000.

When the measurement counter or the time base counter overflows (0xfffff → 0x000000), the RFCnTRG.SREF bit is cleared to 0 and the reference oscillation stops automatically.

The measurement counter overflow sets the RFCnINTF.EREFIF bit to 1 indicating that the reference oscillation has been terminated normally. If the RFCnINTE.EREFIE bit = 1, a reference oscillation completion interrupt request occurs at this point.

The time base counter overflow sets the  $RFC_nINTF.OVTCIF$  bit to 1 indicating that the reference oscillation has been terminated abnormally. If the  $RFC_nINTE.OVTCIE$  bit = 1, a time base counter overflow error interrupt request occurs at this point.

### Sensor oscillation

When the  $RFC_nTRG.SSENA$  bit (sensor A) or the  $RFC_nTRG.SSENB$  bit (sensor B) is set to 1 in Step 7 of the conversion procedure above, the RFC Ch.n starts CR oscillation using the sensor. The measurement counter starts counting up using the CR oscillation clock from 0x000000. The time base counter starts counting down using TCCLK from the value at the end of reference oscillation.

When the time base counter reaches 0x000000 or the measurement counter overflows (0xfffff → 0x000000), the  $RFC_nTRG.SSENA$  bit or the  $RFC_nTRG.SSENB$  bit that started oscillation is cleared to 0 and the sensor oscillation stops automatically.

The time base counter reaching 0x000000 sets the  $RFC_nINTF.ESENAIF$  bit (sensor A) or the  $RFC_nINTF.ESENBIF$  bit (sensor B) to 1 indicating that the sensor oscillation has been terminated normally. If the  $RFC_nINTE.ESENAIE$  bit = 1 or the  $RFC_nINTE.ESENBIE$  bit = 1, a sensor A or sensor B oscillation completion interrupt request occurs at this point.

The measurement counter overflow sets the  $RFC_nINTF.OVMCIF$  to 1 indicating that the sensor oscillation has been terminated abnormally. If the  $RFC_nINTE.OVMCIE$  bit = 1, a measurement counter overflow error interrupt request occurs at this point.

Figure 18.4.4.1 Counter Operations During Reference/Sensor Oscillation

### Forced termination

To abort reference oscillation or sensor oscillation, write 0 to the  $RFC_nTRG.SREF$  bit (reference oscillation), the  $RFC_nTRG.SSENA$  bit (sensor A oscillation), or the  $RFC_nTRG.SSENB$  bit (sensor B oscillation) used to start the oscillation. The counters maintain the value at the point they stopped, note, however, that the conversion results cannot be guaranteed if the oscillation is resumed. When resuming oscillation, execute from counter initialization again.

### Conversion error

Performing reference oscillation and sensor oscillation with the same resistor and capacitor results  $n \approx m$ . The difference between  $n$  and  $m$  is a conversion error. Table 18.4.4.1 lists the error factors. ( $n$ : measurement counter initial value,  $m$ : measurement counter value at the end of sensor oscillation)

Table 18.4.4.1 Error Factors

Error factor	Influence
External part tolerances	Large
Power supply voltage fluctuations	Large
Parasitic capacitance and resistance of the board	Middle
Temperature	Small
Unevenness of IC quality	Small

## 18.4.5 CR Oscillation Frequency Monitoring Function

The CR oscillation clock (RFCLK) generated during converting operation can be output from the RFCLK $n$  pin for monitoring. By setting the RFC $n$ CTL.CONEN bit to 1, the RFC Ch. $n$  enters continuous oscillation mode that disables oscillation stop conditions to continue oscillating operations. In this case, set the the RFC $n$ TRG.SREF bit (reference oscillation), the RFC $n$ TRG.SSENA bit (sensor A oscillation), or the RFC $n$ TRG.SSENB bit (sensor B oscillation) to 1 to start oscillation. Set the bit to 0 to stop oscillation. Using this function helps easily measure the CR oscillation clock frequency. Furthermore, setting the RFC $n$ CTL.RFCLKMD bit to 1 changes the output clock to the divided-by-two RFCLK clock.

Figure 18.4.5.1 CR Oscillation Clock (RFCLK) Waveform

## 18.5 Interrupts

The RFC has a function to generate the interrupts shown in Table 18.5.1.

Table 18.5.1 RFC Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Reference oscillation completion	RFC $n$ INTF.EREFIF	When reference oscillation has been completed normally due to a measurement counter overflow	Writing 1
Sensor A oscillation completion	RFC $n$ INTF.ESENAIF	When sensor A oscillation has been completed normally due to the time base counter reaching 0x000000	Writing 1
Sensor B oscillation completion	RFC $n$ INTF.ESENBIF	When sensor B oscillation has been completed normally due to the time base counter reaching 0x000000	Writing 1
Measurement counter overflow error	RFC $n$ INTF.OVMCIF	When sensor oscillation has been terminated abnormally due to a measurement counter overflow	Writing 1
Time base counter overflow error	RFC $n$ INTF.OVTCIF	When reference oscillation has been terminated abnormally due to a time base counter overflow	Writing 1

The RFC provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 18.6 Control Registers

### RFC Ch.n Clock Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RFCnCLK	15–9	–	0x00	–	R	–
	8	DBRUN	1	H0	R/W	
	7–6	–	0x0	–	R	
	5–4	CLKDIV[1:0]	0x0	H0	R/W	
	3–2	–	0x0	–	R	
	1–0	CLKSRC[1:0]	0x0	H0	R/W	

**Bits 15–9 Reserved**

**Bit 8 DBRUN**

This bit sets whether the RFC operating clock is supplied in DEBUG mode or not.

1 (R/W): Clock supplied in DEBUG mode

0 (R/W): No clock supplied in DEBUG mode

**Bits 7–6 Reserved**

**Bits 5–4 CLKDIV[1:0]**

These bits select the division ratio of the RFC operating clock.

**Bits 3–2 Reserved**

**Bits 1–0 CLKSRC[1:0]**

These bits select the clock source of the RFC.

Table 18.6.1 Clock Source and Division Ratio Settings

RFCnCLK. CLKDIV[1:0] bits	RFCnCLK.CLKSRC[1:0] bits			
	0x0	0x1	0x2	0x3
	IOSC	OSC1	OSC3	EXOSC
0x3	1/8	1/1	1/8	1/1
0x2	1/4		1/4	
0x1	1/2		1/2	
0x0	1/1		1/1	

(Note) The oscillation circuits/external input that are not supported in this IC cannot be selected as the clock source.

**Note:** The RFCnCLK register settings can be altered only when the RFCnCTL.MODEN bit = 0.

### RFC Ch.n Control Register

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
RFCnCTL	15–9	–	0x00	–	R	–
	8	RFCLKMD	0	H0	R/W	
	7	CONEN	0	H0	R/W	
	6	EVTEN	0	H0	R/W	
	5–4	SMODE[1:0]	0x0	H0	R/W	
	3–1	–	0x0	–	R	
	0	MODEN	0	H0	R/W	

**Bits 15–9 Reserved**

**Bit 8 RFCLKMD**

This bit sets the RFCLKOn pin to output the divided-by-two oscillation clock.

1 (R/W): Divided-by-two clock output

0 (R/W): Oscillation clock output

For more information, refer to “CR Oscillation Frequency Monitoring Function.”

**Bit 7 CONEN**

This bit disables the automatic CR oscillation stop function to enable continuous oscillation function.

1 (R/W): Enable continuous oscillation

0 (R/W): Disable continuous oscillation

For more information, refer to “CR Oscillation Frequency Monitoring Function.”

**Bit 6 EVTEN**

This bit enables external clock input mode (event counter mode).

1 (R/W): External clock input mode

0 (R/W): Normal mode

For more information, refer to “Operating Modes.”

**Note:** Do not input an external clock before the  $RFCnCTL.EVTEN$  bit is set to 1. The  $RFINn$  pin is pulled down to  $V_{SS}$  level when the port function is switched for the R/F converter.

**Bits 5–4 SMODE[1:0]**

These bits configure the oscillation mode. For more information, refer to “Operating Modes.”

Table 18.6.2 Oscillation Mode Selection

$RFCnCTL.SMODE[1:0]$ bits	Oscillation mode
0x3, 0x2	Reserved
0x1	AC oscillation mode for resistive sensor measurements
0x0	DC oscillation mode for resistive sensor measurements

**Bits 3–1 Reserved****Bit 0 MODEN**

This bit enables the RFC operations.

1 (R/W): Enable RFC operations (The operating clock is supplied.)

0 (R/W): Disable RFC operations (The operating clock is stopped.)

**Note:** If the  $RFCnCTL.MODEN$  bit is altered from 1 to 0 during R/F conversion, the counter value being converted cannot be guaranteed. R/F conversion cannot be resumed.

**RFC Ch.n Oscillation Trigger Register**

Register name	Bit	Bit name	Initial	Reset	R/W	Remarks
$RFCnTRG$	15–8	–	0x00	–	R	–
	7–3	–	0x00	–	R	
	2	SSENB	0	H0	R/W	
	1	SSENA	0	H0	R/W	
	0	SREF	0	H0	R/W	

**Bits 15–3 Reserved****Bit 2 SSENB**

This bit controls CR oscillation for sensor B. This bit also indicates the CR oscillation status.

1 (W): Start oscillation

0 (W): Stop oscillation

1 (R): Being oscillated

0 (R): Stopped

**Note:** Writing 1 to the  $RFCnTRG.SSENB$  bit does not start oscillation when the  $RFCnCTL.SMODE[1:0]$  bits = 0x1 (AC oscillation mode for resistive sensor measurements).

**Bit 1 SSENA**

This bit controls CR oscillation for sensor A. This bit also indicates the CR oscillation status.

1 (W): Start oscillation

0 (W): Stop oscillation

1 (R): Being oscillated

0 (R): Stopped

## 18 R/F CONVERTER (RFC)

### Bit 0 SREF

This bit controls CR oscillation for the reference resistor. This bit also indicates the CR oscillation status.

- 1 (W): Start oscillation
- 0 (W): Stop oscillation
- 1 (R): Being oscillated
- 0 (R): Stopped

- Notes:**
- Settings in this register are all ineffective when the RFCnCTL.MODEN bit = 0 (RFC operation disabled).
  - When writing 1 to the RFCnTRG.SREF bit, the RFCnTRG.SSENA bit, or the RFCnTRG.SSENB bit to start oscillation, be sure to avoid having more than one bit set to 1.
  - Be sure to clear the interrupt flags (RFCnINTF.EREFIF bit, RFCnINTF.ESENAIF bit, RFCnINTF.ESENBIF bit, RFCnINTF.OVMCIF bit, and RFCnINTF.OVTCIF bit) before starting oscillation using this register.

## RFC Ch.n Measurement Counter Low and High Registers

<b>Bit 3</b>	<b>OVMCIF</b>
<b>Bit 2</b>	<b>ESENBIF</b>
<b>Bit 1</b>	<b>ESENAIF</b>
<b>Bit 0</b>	<b>EREFIF</b>

These bits indicate the RFC interrupt cause occurrence status.

- 1 (R): Cause of interrupt occurred
- 0 (R): No cause of interrupt occurred
- 1 (W): Clear flag
- 0 (W): Ineffective

The following shows the correspondence between the bit and interrupt:

- RFCnINTF.OVTCIF bit: Time base counter overflow error interrupt
- RFCnINTF.OVMCIF bit: Measurement counter overflow error interrupt
- RFCnINTF.ESENBIF bit: Sensor B oscillation completion interrupt
- RFCnINTF.ESENAIF bit: Sensor A oscillation completion interrupt
- RFCnINTF.EREFIF bit: Reference oscillation completion interrupt

# 19 12-bit A/D Converter (ADC12A)

## 19.1 Overview

The ADC12A is a successive approximation type 12-bit A/D converter.

The features of the ADC12A are listed below.

- Conversion method: Successive approximation type
- Resolution: 12 bits
- Analog input voltage range: Reference voltage VREFA to Vss
- Supports two conversion modes:
  1. One-time conversion mode
  2. Continuous conversion mode
- Supports three conversion triggers:
  1. Software trigger
  2. 16-bit timer underflow trigger
  3. External trigger
- Can convert multiple analog input signals sequentially.
- Can generate conversion completion and overwrite error interrupts.

Figure 19.1.1 shows the ADC12A configuration.

Table 19.1.1 ADC12A Configuration of S1C17W03/W04

Item	32-pin package	48-pin package/chip
Number of channels	1 channel (Ch.0)	
Number of analog signal inputs per channel	Ch.0: 5 inputs (ADIN00–02, ADIN04–05)	Ch.0: 6 inputs (ADIN00–ADIN05)
16-bit timer used as conversion clock and trigger sources	Ch.0 ← 16-bit timer Ch.3	
VREFA pin (external reference voltage input)	Not available (Connected to VDDA inside the IC.)	Available

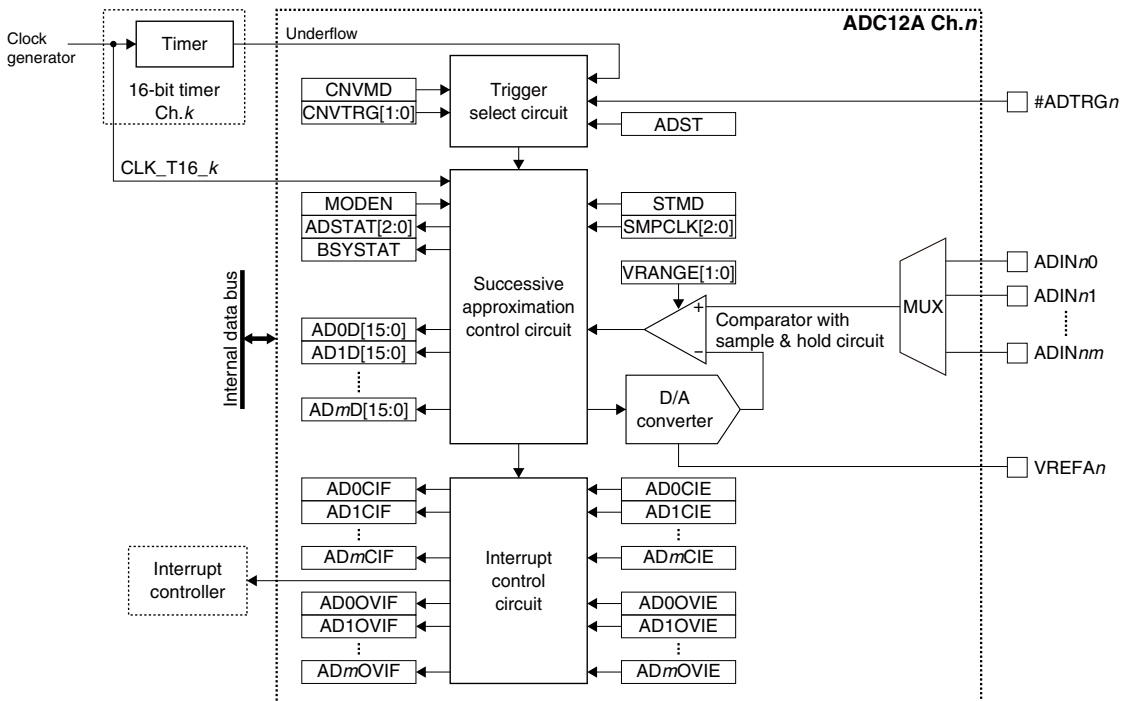

Figure 19.1.1 ADC12A Configuration

**Note:** In this chapter,  $n$ ,  $m$ , and  $k$  refer to an ADC12A channel number, an analog input pin number, and a 16-bit timer channel number, respectively.

## 19.2 Input Pins and External Connections

### 19.2.1 List of Input Pins

Table 19.2.1.1 lists the ADC12A pins.

Table 19.2.1.1 List of ADC12A Pins

Pin name	I/O*	Initial status*	Function
ADIN $n$ m	A	Hi-Z	Analog signal input
#ADTRG $n$	I	I	External trigger input
VREFA $n$	A	Hi-Z	Reference voltage input

\* Indicates the status when the pin is configured for the ADC12A.

If the port is shared with the ADC12A pin and other functions, the ADC12A input function must be assigned to the port before activating the ADC12A. For more information, refer to the “I/O Ports” chapter.

### 19.2.2 External Connections

Figure 19.2.2.1 shows a connection diagram between the ADC12A and external devices.

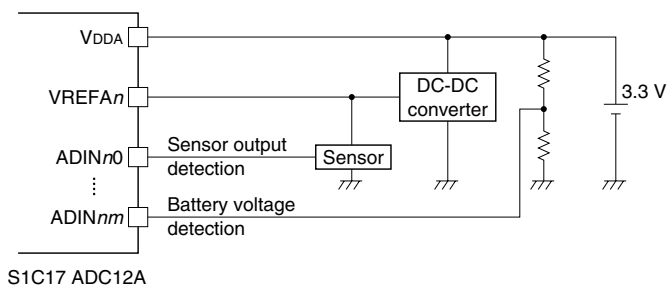

Figure 19.2.2.1 Connections between ADC12A and External Devices

## 19.3 Clock Settings

### 19.3.1 ADC12A Operating Clock

The 16-bit timer Ch.k operating clock CLK\_T16\_k is also used as the ADC12A operating clock. For more information on the CLK\_T16\_k settings and clock supply in SLEEP and DEBUG modes, refer to “Clock Settings” in the “16-bit Timers” chapter.

**Note:** When the CLK\_T16\_k supply stops during A/D conversion (e.g., when the CPU enters SLEEP or DEBUG mode), correct conversion results cannot be obtained even if the clock supply is resumed after that. In this case, perform A/D conversion again.

### 19.3.2 Sampling Time

The ADC12A includes a sample and hold circuit. The sampling time must be set so that it will satisfy the time required for acquiring input voltage ( $t_{ACQ}$ : acquisition time). Figure 19.3.2.1 shows an equivalent circuit of the analog input portion.

Figure 19.3.2.1 Equivalent Circuit of Analog Input Portion

For the  $R_{ADIN}$  and  $C_{ADIN}$  values in the equivalent circuit, refer to “12-bit A/D Converter Characteristics” in the “Electrical Characteristics” chapter. Based on these values, configure the ADC12A operating clock  $CLK\_T16\_k$  and the  $ADC12\_nTRG.SMPCLK[2:0]$  bits that set the sampling time so that these settings will satisfy the equations shown below.

$$t_{ACQ} = 8 \times (R_S + R_{ADIN}) \times C_{ADIN} \quad (\text{Eq. 19.1})$$

$$\frac{1}{f_{CLK\_ADC}} \times SMPCLK > t_{ACQ} \quad (\text{Eq. 19.2})$$

Where

$f_{CLK\_ADC}$ :  $CLK\_T16\_k$  frequency [Hz]

$SMPCLK$ : Sampling time =  $ADC12\_nTRG.SMPCLK[2:0]$  bit-setting (4 to 11  $CLK\_T16\_k$  cycles)

The following shows the relationship between the sampling time and the maximum sampling rate.

$$\text{Maximum sampling rate [sps]} = \frac{f_{CLK\_ADC}}{SMPCLK + 13} \quad (\text{Eq. 19.3})$$

## 19.4 Operations

### 19.4.1 Initialization

The ADC12A should be initialized with the procedure shown below.

1. Assign the ADC12A input function to the ports. (Refer to the “I/O Ports” chapter.)
2. Configure the 16-bit timer  $Ch.k$  operating clock so that it will satisfy the sampling time.
3. Set the  $ADC12\_nCTL.MODEN$  bit to 1. (Enable ADC12A operations)
4. Configure the following  $ADC12\_nTRG$  register bits:
  - $ADC12\_nTRG.SMPCLK[2:0]$  bits (Set sampling time)
  - $ADC12\_nTRG.CNVTRG[1:0]$  bits (Select conversion start trigger source)
  - $ADC12\_nTRG.CNVMD$  bit (Set conversion mode)
  - $ADC12\_nTRG.STMD$  bit (Set data storing mode)
  - $ADC12\_nTRG.STAAIN[2:0]$  bits (Set analog input pin to be A/D converted first)
  - $ADC12\_nTRG.ENDAIN[2:0]$  bits (Set analog input pin to be A/D converted last)
5. Set the  $ADC12\_nCFG.VRANGE[1:0]$  bits to 0x3. (Set operating voltage range according to  $V_{DDA}$ )
6. Set the following bits when using the interrupt:
  - Write 1 to the interrupt flags in the  $ADC12\_nINTF$  register. (Clear interrupt flags)
  - Set the interrupt enable bits in the  $ADC12\_nINTE$  register to 1. (Enable interrupts)

### 19.4.2 Conversion Start Trigger Source

The trigger source, which starts A/D conversion, can be selected from the three types shown below using the  $ADC12\_nTRG.CNVTRG[1:0]$  bits.

#### External trigger (#ADTRG $n$ pin)

Writing 1 to the  $ADC12\_nCTL.ADST$  bit enables the ADC12A to accept trigger inputs. After that, the falling edge of the signal input to the #ADTRG $n$  pin starts A/D conversion.

#### 16-bit timer $Ch.k$ underflow trigger

Writing 1 to the  $ADC12\_nCTL.ADST$  bit enables the ADC12A to accept trigger inputs. After that, A/D conversion is started when an underflow occurs in the 16-bit timer  $Ch.k$ .

#### Software trigger

Writing 1 to the  $ADC12\_nCTL.ADST$  bit starts A/D conversion.

Trigger inputs can be accepted while the  $ADC12\_nCTL.BSYSTAT$  bit is set to 0 and are ignored while set to 1. A/D conversion is actually started in sync with  $CLK\_T16\_k$  after a trigger is accepted.

Writing 0 to the  $ADC12\_nCTL.ADST$  bit stops A/D conversion after the one currently being executed has completed.

### 19.4.3 Conversion Mode and Analog Input Pin Settings

The ADC12A can be put into two conversion modes shown below using the ADC12\_nTRG.CNVMD bit. Each mode allows setting of analog input pin range to be A/D converted. The analog input pin range can be set using the ADC12\_nTRG.STAIN[2:0] bits for specifying the first analog input pin and the ADC12\_nTRG.ENDAIN[2:0] bits for specifying the last analog input pin. The analog input signals within the specified range are A/D converted successively in ascending order of the pin numbers.

#### One-time conversion mode

Once the ADC12A executes A/D conversion for all the analog input signals within the specified range, it is automatically stopped.

#### Continuous conversion mode

The ADC12A repeatedly executes A/D conversion within the specified range until 0 is written to the ADC12\_nCTL.ADST bit.

### 19.4.4 A/D Conversion Operations and Control Procedures

The following shows A/D conversion control procedures and the ADC12A operations.

#### Control procedure in one-time conversion mode

1. Write 1 to the ADC12\_nCTL.ADST bit.
2. Wait for an ADC12A interrupt.
  - i. If the ADC12\_nINTF.ADMCIF bit = 1 (analog input signal *m* A/D conversion completion interrupt), clear the ADC12\_nINTF.ADMCIF bit and then go to Step 3.
  - ii. If the ADC12\_nINTF.ADMOVIF bit = 1 (analog input signal *m* A/D conversion result overwrite error interrupt), clear the ADC12\_nINTF.ADMOVIF bit and terminate as an error or retry A/D conversion.
3. Read the A/D conversion result of the analog input *m* (ADC12\_nADM.DADM[15:0] bits).
  - \* The 12-bit conversion results are located at the low-order 12 bits or high-order 12-bits within the ADC12\_nADM.DADM[15:0] bits according to the ADC12\_nTRG.STMD bit setting.
4. Repeat Steps 2 and 3 until A/D conversion for all the analog input pins within the specified range is completed.
5. To forcefully terminate the A/D conversion being executed, write 0 to the ADC12\_nCTL.ADST bit.  
The ADC12A stops operating after the A/D conversion currently being executed has completed.  
The ADC12\_nCTL.ADST bit must be cleared by writing 0 even if A/D conversion is completed and automatically stopped.

#### Control procedure in continuous conversion mode

1. Write 1 to the ADC12\_nCTL.ADST bit.
2. Wait for an ADC12A interrupt.
  - i. If the ADC12\_nINTF.ADMCIF bit = 1 (analog input signal *m* A/D conversion completion interrupt), clear the ADC12\_nINTF.ADMCIF bit and then go to Step 3.
  - ii. If the ADC12\_nINTF.ADMOVIF bit = 1 (analog input signal *m* A/D conversion result overwrite error interrupt), clear the ADC12\_nINTF.ADMOVIF bit and terminate as an error or retry A/D conversion.
3. Read the A/D conversion result of the analog input *m* (ADC12\_nADM.DADM[15:0] bits).
4. Repeat Steps 2 and 3 until terminating A/D conversion.
5. Write 0 to the ADC12\_nCTL.ADST bit.  
The ADC12A stops operating after the A/D conversion currently being executed has completed.

## 19.5 Interrupts

The ADC12A has a function to generate the interrupts shown in Table 19.5.1.

Table 19.5.1 ADC12A Interrupt Function

Interrupt	Interrupt flag	Set condition	Clear condition
Analog input signal <i>m</i> A/D conversion completion	ADC12_nINTF.ADMCIF	When an analog input signal <i>m</i> A/D conversion result is loaded to the ADC12_nADMd register	Writing 1
Analog input signal <i>m</i> A/D conversion result overwrite error	ADC12_nINTF.ADMOVIF	When a new A/D conversion result is loaded to the ADC12_nADMd register while the ADC12_nINTF.ADMCIF bit = 1	Writing 1

Note that the A/D conversion continues even if an A/D conversion result overwrite error has occurred. A/D conversion result overwrite errors are decided regardless of whether the ADC12\_nADMd register has been read or not.

The ADC12A provides interrupt enable bits corresponding to each interrupt flag. An interrupt request is sent to the interrupt controller only when the interrupt flag, of which interrupt has been enabled by the interrupt enable bit, is set. For more information on interrupt control, refer to the “Interrupt Controller” chapter.

## 19.6 Control Registers

### ADC12A Ch.*n* Control Register

0	MODEN	0	H0	R/W		

**Bit 15**      **Reserved**

#### Bits 14–12 ADSTAT[2:0]

These bits indicate the analog input pin number *m* being A/D converted.

Table 19.6.1 Relationship Between Control Bit Value and Analog Input Pin

ADC12_nCTL.ADSTAT[2:0] bits ADC12_nTRG.STAAIN[2:0] bits ADC12_nTRG.ENDAIN[2:0] bits	Analog input pin

0x5	ADIN <sub><i>n</i>5</sub>
0x4	ADIN <sub><i>n</i>4</sub>
0x3	ADIN <sub><i>n</i>3</sub>
0x2	ADIN <sub><i>n</i>2</sub>
0x1	ADIN <sub><i>n</i>1</sub>
0x0	ADIN <sub><i>n</i>0</sub>

These bits indicate the last converted analog input pin number after A/D conversion is forcefully terminated by writing 0 to the ADC12\_nCTL.ADST bit or automatically terminated in one-time conversion mode (ADC12\_nTRG.CNVMD = 0). If A/D conversion is stopped after the maximum analog input pin number (different in each model) has been completed, these bits indicate ADIN<sub>*n*0</sub>.

**Bit 11**      **Reserved**

**Bit 10 BSYSSTAT**

This bit indicates whether the ADC12A is executing A/D conversion or not.

1 (R/W): A/D converting

0 (R/W): Idle

**Note:** The ADC12\_nCTL.BSYSSTAT bit is cleared to 0 when the clock is supplied to ADC12A by setting the ADC12\_nCTL.MODEN bit to 1.

**Bits 9–2 Reserved****Bit 1 ADST**

This bit starts A/D conversion or enables to accept triggers.

1 (R/W): Start sampling and conversion (software trigger)/

Enable trigger acceptance (external trigger, 16-bit timer underflow trigger)

0 (R/W): Terminate conversion

This bit does not revert to 0 automatically after A/D conversion has completed. Write 0 to this bit once and write 1 again to start another A/D conversion. After 0 is written to this bit to forcefully terminate conversion, the ADC12A stops after the A/D conversion being executed is completed. Therefore, this bit cannot be used to determine whether the ADC12A is executing A/D conversion or not.

**Note:** The data written to the ADC12\_nCTL.ADST bit must be retained for one or more CLK\_T16\_k clock cycles when 1 is written or two or more CLK\_T16\_k clock cycles when 0 is written.

**Bit 0 MODEN**

This bit enables the ADC12A operations.

1 (R/W): Enable ADC12A operations (The operating clock is supplied.)

0 (R/W): Disable ADC12A operations (The operating clock is stopped.)

**Note:** After 0 is written to the ADC12\_nCTL.MODEN bit, the ADC12A executes a terminate processing. Before the clock source is deactivated, read the ADC12\_nCTL.MODEN bit to make sure that it is set to 0.

**Bits 15–14 Reserved****Bits 13–11 ENDAIN[2:0]**

These bits set the analog input pin to be A/D converted last.

See Table 19.6.1 for the relationship between analog input pins and bit setting values.

**Note:** The analog input pin range to perform A/D conversion must be set as ADC12\_nTRG.ENDAIN[2:0] bits  $\geq$  ADC12\_nTRG.STAAIN[2:0] bits.

**Bits 10–8 STAAIN[2:0]**

These bits set the analog input pin to be A/D converted first.

See Table 19.6.1 for the relationship between analog input pins and bit setting values.

**Bit 7 STMD**

This bit selects the data alignment when the conversion results are loaded into the A/D conversion result registers (ADC12\_nADmD.ADmD[15:0] bits).

1 (R/W): Left justify

0 (R/W): Right justify

All the A/D conversion result registers change their data alignment immediately after this bit is altered. This does not affect the conversion results.

# 20 Multiplier/Divider (COPRO2)

## 20.1 Overview

COPRO2 is the coprocessor that provides multiplier/divider functions. The features of COPRO2 are listed below.

- **Multiplication:** Supports signed/unsigned multiplications.  
(16 bits × 16 bits = 32 bits)  
Can be executed in 1 cycle.
- **Multiplication and accumulation (MAC):** Supports signed/unsigned MAC operations with overflow detection function. (16 bits × 16 bits + 32 bits = 32 bits)  
Can be executed in 1 cycle.
- **Division:** Supports signed/unsigned divisions.  
(32 bits ÷ 32 bits = 32 bits with 32-bit remainder)  
Can be executed in 17 to 20 cycles.  
Overflow detection and division by zero processing are not supported.

Figure 20.1.1 shows the COPRO2 configuration.

Figure 20.1.1 COPRO2 Configuration

## 20.2 Operation Mode and Output Mode

COPRO2 operates according to the operation mode specified by the application program. As listed in Table 20.2.1, COPRO2 supports 11 operations.

The multiplication, division and MAC results are 32-bit data, therefore, the S1C17 Core cannot read them in one access cycle. The output mode is provided to specify the high-order 16 bits or low-order 16 bits of the operation result register 0 or 1 to be read from COPRO2.

The operation and output modes can be specified with a 7-bit data by writing it to the mode setting register in COPRO2. Use a “ld.cw” instruction for this writing.

```
ld.cw %rd, %rs    %rs[6:0] is written to the mode setting register. (%rd: not used)
ld.cw %rd, imm7  imm7[6:0] is written to the mode setting register. (%rd: not used)
```

## 20.3 Multiplication

The multiplication function performs “A (32 bits) = B (16 bits) × C (16 bits).”

The following shows a procedure to perform a multiplication:

1. Set the mode to 0x04 (unsigned multiplication, 16 low-order bits output mode 0) or 0x05 (signed multiplication, 16 low-order bits output mode 0).
2. Send the 16-bit multiplicand (B) and 16-bit multiplier (C) to COPRO2 using a “ld.ca” instruction.
3. Read the one-half result (16 low-order bits = A[15:0]) and the flag status.
4. Set the mode to 0x13 (operation result read, 16 high-order bits output mode 0).
5. Read another one-half result (16 high-order bits = A[31:16]).

## 20.4 Division

The division function performs “A (32 bits) = B (32 bits) ÷ C (32 bits), D (32 bits) = remainder.”

The following shows a procedure to perform a division:

1. Set the mode to 0x02 (initialize mode 2).
2. Set the 32-bit dividend (B) to the operation result register 0 using a “ld.cf” instruction.
3. Set the mode to 0x08 (unsigned division, 16 low-order bits output mode 0) or 0x09 (signed division, 16 low-order bits output mode 0).
4. Send the 32-bit divisor (C) to COPRO2 using a “ld.ca” instruction.
5. Read the one-half result (16 low-order bits = A[15:0]) of the operation result register 0 (quotient) and the flag status.
6. Set the mode to 0x13 (operation result read, 16 high-order bits output mode 0).
7. Read another one-half result (16 high-order bits = A[31:16]) of the operation result register 0 (quotient).
8. Set the mode to 0x23 (operation result read, 16 low-order bits output mode 1).
9. Read the one-half result (16 low-order bits = D[15:0]) of the operation result register 1 (remainder).
10. Set the mode to 0x33 (operation result read, 16 high-order bits output mode 1).
11. Read another one-half result (16 high-order bits = D[31:16]) of the operation result register 1 (remainder).

```

## 20.5 MAC

The MAC (multiplication and accumulation) function performs “A (32 bits) = B (16 bits) × C (16 bits) + A (32 bits).”

The following shows a procedure to perform a MAC operation:

- Set the initial value (A) to the operation result register 0.
  - To clear the operation result registers (A = 0):  
Set the mode to 0x00 (initialize mode 0). (It is not necessary to send 0x00 to COPRO2 with another instruction.)
  - To load a 16-bit value to the operation result register 0:  
Set the operation mode to 0x01 (initialize mode 1) and then send the initial value (16 bits) to COPRO2 using a “ld.cf” instruction.
  - To load a 32-bit value to the operation result register 0:  
Set the operation mode to 0x02 (initialize mode 2) and then send the initial value (32 bits) to COPRO2 using a “ld.cf” instruction.
- Set the mode to 0x06 (unsigned MAC, 16 low-order bits output mode 0) or 0x07 (signed MAC, 16 low-order bits output mode 0).
- Repeat sending the 16-bit multiplicand (B) and 16-bit multiplier (C) to COPRO2 the number of times required using a “ld.ca” instruction.
- Read the one-half result (16 low-order bits = A[15:0]) and the flag status.
- Set the mode to 0x13 (operation result read, 16 high-order bits output mode).
- Read another one-half result (16 high-order bits = A[31:16]).

Example:

- ld.cw %r0,0x00 ; Sets the mode (initialize mode 0) to clear the operation result register 0 to 0x0000.
- ld.cw %r0,0x07 ; Sets the mode (signed MAC mode and 16 low-order bits output mode 0).
- ld.ca %r0,%r1 ; Performs “res0[31:0] = %r0[15:0] × %r1[15:0] + res0[31:0]” and loads the 16 low-order bits of the result to %r0.
- ld.cw %r0,0x13 ; Sets the mode (operation result read mode and 16 high-order bits output mode 0).
- ld.ca %r1,%r0 ; Loads the 16 high-order bits of the result to %r1.

## Conditions to set the overflow (V) flag

An overflow occurs in a signed MAC operation and the overflow (V) flag is set to 1 when the signs of the multiplication result, operation result register value, and multiplication & accumulation result match the following conditions:

Table 20.5.3 Conditions to Set the Overflow (V) Flag

Mode setting value	Sign of multiplication result	Sign of operation result register value	Sign of multiplication & accumulation result
0x07	0 (positive)	0 (positive)	1 (negative)
0x07	1 (negative)	1 (negative)	0 (positive)

An overflow occurs when a MAC operation performs addition of positive values and a negative value results, or it performs addition of negative values and a positive value results. The coprocessor holds the operation result until the overflow (V) flag is cleared.

## Conditions to clear the overflow (V) flag

The overflow (V) flag that has been set will be cleared when an overflow has not been occurred during execution of the “ld.ca” instruction for MAC operation or when the “ld.ca” or “ld.cf” instruction is executed in an operation mode other than operation result read mode.

## 20.6 Reading Operation Results

The “ld.ca” instruction cannot load a 32-bit operation result to a CPU register, so a multiplication, division or MAC operation returns the one-half (16 bits according to the output mode) result (A[15:0] or A[31:16]) and the flag status to the CPU registers. Another one-half should be read by setting COPRO2 into operation result read mode. The operation result register keeps the loaded operation result until it is rewritten by other operation.

# Appendix B Power Saving

Current consumption will vary dramatically, depending on CPU operating mode, operation clock frequency, peripheral circuits being operated, and power generator operating mode. Listed below are the control methods for saving power.

## B.1 Operating Status Configuration Examples for Power Saving

Table B.1.1 lists typical examples of operating status configuration with consideration given to power saving.

Table B.1.1 Typical Operating Status Configuration Examples

Operating status configuration	Current consumption	PWG2	OSC1	IOSC/OSC3/EXOSC	RTCA	CPU	Current consumption listed in electrical characteristics
Standby	↑ Low	Super economy/ Economy	OFF	OFF	OFF	SLEEP	I <sub>SLP</sub>
Clock counting						SLEEP or HALT	I <sub>HALT2</sub>
Low-speed processing			OSC1 RUN	I <sub>RUN20</sub>			
Peripheral circuit operations	High ↓	Normal	ON	ON	ON	SLEEP or HALT	I <sub>HALT1</sub>
High-speed processing						IOSC/OSC3/EXOSC RUN	I <sub>RUN10</sub>

**Note:** The 32-pin package model does not support super economy mode.

If the current consumption order by the operating status configuration shown in Table B.1.1 is different from one that is listed in “Electrical Characteristics,” check the settings shown below.

### PWGCTL.PWGMOD[2:0] bits of the power generator

If the PWGCTL.PWGMOD[2:0] bits of the power generator is 0x2 (normal mode) when the CPU enters SLEEP mode, current consumption in SLEEP mode will be larger than I<sub>SLP</sub> that is listed in “Electrical Characteristics.” Set the PWGCTL.PWGMOD[2:0] bits to 0x5 (super economy mode), 0x3 (economy mode), or 0x0 (automatic mode) before executing the slp instruction.

### CLGOSC.IOSCSLPC/OSC1SLPC/OSC3SLPC/EXOSCSLPC bits of the clock generator

Setting the CLGOSC.IOSCSLPC, OSC1SLPC, OSC3SLPC, or EXOSCSLPC bit of the clock generator to 0 disables the oscillator circuit stop control when the slp instruction is executed. To stop the oscillator circuits during SLEEP mode, set these bits to 1.

### MODEN bits of the peripheral circuits

Setting the MODEN bit of each peripheral circuit to 1 starts supplying the operating clock enabling the peripheral circuit to operate. To reduce current consumption, set the MODEN bits of unnecessary peripheral circuits to 0. Note that the real-time clock has no MODEN bit, therefore, current consumption does not vary if it is counting or idle.

### OSC1 oscillator circuit configurations

The OSC1 oscillator circuit provides some configuration items to support various crystal resonators with ranges from cylinder type through surface-mount type. These configurations trade off current consumption for performance as shown below.

- The lower oscillation inverter gain setting (CLGOSC1.INV1B[1:0]/INV1N[1:0] bits) decreases current consumption.
- The lower OSC1 internal gate capacitance setting (CLGOSC1.CGI1[2:0] bits) decreases current consumption.
- Using lower OSC1 external gate and drain capacitances decreases current consumption.
- Using a crystal resonator with lower C<sub>L</sub> value decreases current consumption.

However, these configurations may reduce the oscillation margin and increase the frequency error, therefore, be sure to perform matching evaluation using the actual printed circuit board.

### OSC3 (crystal/ceramic) oscillator circuit configurations

The OSC3 (crystal/ceramic) oscillator circuit provides some configuration items to support various crystal and ceramic resonators. These configurations trade off current consumption for performance as shown below.

- The lower oscillation inverter gain setting (CLGOSC3.OSC3INV[1:0] bits) decreases current consumption.
- Using lower OSC3 external gate and drain capacitances decreases current consumption.
- Using a resonator with lower CL value decreases current consumption.

However, these configurations may reduce the oscillation margin and increase the frequency error, therefore, be sure to perform matching evaluation using the actual printed circuit board.

## B.2 Other Power Saving Methods

---

### Supply voltage detector configuration

Continuous operation mode (SVDCTL.SVDMD[1:0] bits = 0x0) always detects the power supply voltage, therefore, it increases current consumption. Set the supply voltage detector to intermittent operation mode or turn it on only when required.

# Appendix C Mounting Precautions

This section describes various precautions for circuit board design and IC mounting.

## OSC1/OSC3 oscillator circuit

- Oscillation characteristics depend on factors such as components used (resonator,  $C_G$ ,  $C_D$ ) and circuit board patterns. In particular, with crystal resonators, select the appropriate capacitors ( $C_G$ ,  $C_D$ ) only after fully evaluating components actually mounted on the circuit board.
- Oscillator clock disturbances caused by noise may cause malfunctions. To prevent such disturbances, consider the following points.
  - (1) Components such as a resonator, resistors, and capacitors connected to the OSC1 (OSC3) and OSC2 (OSC4) pins should have the shortest connections possible.
  - (2) Wherever possible, avoid locating digital signal lines within 3 mm of the OSC1 (OSC3) and OSC2 (OSC4) pins or related circuit components and wiring. Rapidly-switching signals, in particular, should be kept at a distance from these components. Since the spacing between layers of multi-layer printed circuit boards is a mere 0.1 mm to 0.2 mm, the above precautions also apply when positioning digital signal lines on other layers. Never place digital signal lines alongside such components or wiring, even if more than 3 mm distance or located on other layers. Avoid crossing wires.

- (3) Use Vss to shield the OSC1 (OSC3) and OSC2 (OSC4) pins and related wiring (including wiring for adjacent circuit board layers). Layers wired should be adequately shielded as shown to the right. Fully ground adjacent layers, where possible. At minimum, shield the area at least 5 mm around the above pins and wiring.

Even after implementing these precautions, avoid configuring digital signal lines in parallel, as described in (2) above. Avoid crossing even on discrete layers, except for lines carrying signals with low switching frequencies.

- (4) After implementing these precautions, check the FOUT pin output clock waveform by running the actual application program within the product.

For the OSC1 waveform, enlarge the areas before and after the clock rising and falling edges and take special care to confirm that the regions approximately 100 ns to either side are free of clock or spiking noise. For the OSC3 waveform, confirm that the frequency is as designed, is free of noise, and has minimal jitter.

Failure to observe precautions (1) to (3) adequately may lead to noise in OSC1CLK and jitter in OSC3CLK. Noise in the OSC1CLK will destabilize timers that use OSC1CLK as well as CPU Core operations. Jitter in the OSC3 output will reduce operating frequencies.

## #RESET pin

Components such as a switch and resistor connected to the #RESET pin should have the shortest connections possible to prevent noise-induced resets.

## VPP pin

If fluctuations in the Flash programming voltage  $V_{PP}$  is large, connect a capacitor  $C_{VPP}$  between the Vss and  $V_{PP}$  pins to suppress fluctuations within  $V_{PP} \pm 1$  V. The  $C_{VPP}$  should be placed as close to the  $V_{PP}$  pin as possible and use a sufficiently thick wiring pattern that allows current of several tens of mA to flow.

## Power supply circuit

Sudden power supply fluctuations due to noise will cause malfunctions. Consider the following issues.

- (1) Connections from the power supply to the  $V_{DD}/V_{DDA}$  and Vss pins should be implemented via the shortest, thickest patterns possible.

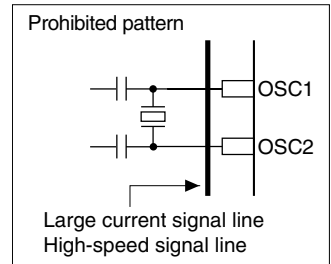

## APPENDIX C MOUNTING PRECAUTIONS

- (2) If a bypass capacitor is connected between  $V_{DD}/V_{DDA}$  and  $V_{SS}$ , connections between the  $V_{DD}/V_{DDA}$  and  $V_{SS}$  pins should be as short as possible.

### Signal line location

- To prevent electromagnetically-induced noise arising from mutual induction, large-current signal lines should not be positioned close to pins susceptible to noise, such as oscillator and analog measurement pins.
- Locating signal lines in parallel over significant distances or crossing signal lines operating at high speed will cause malfunctions due to noise generated by mutual interference.

### Handling of light (for bare chip mounting)

The characteristics of semiconductor components can vary when exposed to light. ICs may malfunction or non-volatile memory data may be corrupted if ICs are exposed to light.

Consider the following precautions for circuit boards and products in which this IC is mounted to prevent IC malfunctions attributable to light exposure.

- (1) Design and mount the product so that the IC is shielded from light during use.
- (2) Shield the IC from light during inspection processes.
- (3) Shield the IC on the upper, underside, and side faces of the IC chip.
- (4) Mount the IC chip within one week of opening the package. If the IC chip must be stored before mounting, take measures to ensure light shielding.
- (5) Adequate evaluations are required to assess nonvolatile memory data retention characteristics before product delivery if the product is subjected to heat stress exceeding regular reflow conditions during mounting processes.

### Unused pins

- (1) I/O port (P) pins

Unused pins should be left open. The control registers should be fixed at the initial status.

- (2) OSC1, OSC2, OSC3, OSC4, and EXOSC pins

If the OSC1 oscillator circuit, OSC3 oscillator circuit or EXOSC input circuit is not used, the OSC1 and OSC2 pins, the OSC3 and OSC4 pins, or the EXOSC pin should be left open. The control registers should be fixed at the initial status (disabled).

- (3)  $CV_{1-2}$  and  $VD_2$  pins

If super economy mode is not used, the  $CV_1$  and  $CV_2$  pins should be left open. In this case,  $CPW_3$  can be omitted by connecting between the  $V_{DD}$  and  $VD_2$  pins directly. When these pins are not short-circuited,  $CPW_3$  is required even if super economy mode is not used.

- (4) VREFA0 pin

If the 12-bit A/D converter is not used, the VREFA0 pin should be left open.

### Miscellaneous

Minor variations over time may result in electrical damage arising from disturbances in the form of voltages exceeding the absolute maximum rating when mounting the product in addition to physical damage. The following factors can give rise to these variations:

- (1) Electromagnetically-induced noise from industrial power supplies used in mounting reflow, reworking after mounting, and individual characteristic evaluation (testing) processes
- (2) Electromagnetically-induced noise from a solder iron when soldering

In particular, during soldering, take care to ensure that the soldering iron GND (tip potential) has the same potential as the IC GND.

# Appendix D Measures Against Noise

To improve noise immunity, take measures against noise as follows:

## Noise Measures for V<sub>DD</sub>, V<sub>DDA</sub>, and V<sub>SS</sub> Power Supply Pins

When noise falling below the rated voltage is input, an IC malfunction may occur. If desired operations cannot be achieved, take measures against noise on the circuit board, such as designing close patterns for circuit board power supply circuits, adding noise-filtering decoupling capacitors, and adding surge/noise prevention components on the power supply line.

For the recommended patterns on the circuit board, see “Mounting Precautions” in Appendix.

## Noise Measures for #RESET Pin

If noise is input to the #RESET pin, the IC may be reset. Therefore, the circuit board must be designed properly taking noise measures into consideration.

For the recommended patterns on the circuit board, see “Mounting Precautions” in Appendix.

## Noise Measures for Oscillator Pins

The oscillator input pins must pass a signal of small amplitude, so they are hypersensitive to noise. Therefore, the circuit board must be designed properly taking noise measures into consideration.

For the recommended patterns on the circuit board, see “Mounting Precautions” in Appendix.

## Noise Measures for Debug Pins

This product provides the input/output pins (DCLK, DST2, and DSIO) to connect ICDmini (S5U1C17001H) for debugging. If noise is input to these pins with the debugging function enabled, the S1C17 Core may enter DEBUG mode. To prevent unexpected transitions to DEBUG mode caused by extraneous noise, switch the DCLK, DST2, and DSIO pins to general-purpose I/O port pins within the initialization routine when the debug functions are not used.

For details of the pin functions and the function switch control, see the “I/O Ports” chapter.

**Note:** Do not perform the function switching shown above when the application is under development, as the debug functions must be used. The debugging cannot be performed after the pin function is switched. The above processing must be added after the application development has completed and debugging is no longer necessary.

The DSIO pin should be pulled up with a 10 kΩ resistor when using the debug pin functions.

## Noise Measures for Interrupt Input Pins

This product is able to generate a port input interrupt when the input signal changes. The interrupt is generated when an input signal edge is detected, therefore, an interrupt may occur if the signal changes due to extraneous noise. To prevent occurrence of unexpected interrupts due to extraneous noise, enable the chattering filter circuit when using the port input interrupt.

For details of the port input interrupt and chattering filter circuit, see the “I/O Ports” chapter.

## Noise Measures for UART Pins

This product includes a UART for asynchronous communications. The UART starts receive operation when it detects a low level input from the SIN<sub>n</sub> pin. Therefore, a receive operation may be started if the SIN<sub>n</sub> pin is set to low due to extraneous noise. In this case, a receive error will occur or invalid data will be received.

To prevent the UART from malfunction caused by extraneous noise, take the following measures:

- Stop the UART operations while asynchronous communication is not performed.
- Execute the resending process via software after executing the receive error handler with a parity check.

For details of the pin functions and the function switch control, see the “I/O Ports” chapter. For the UART control and details of receive errors, see the “UART” chapter.
